Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This research focused on developing a centralized system for monitoring and forecasting dengue trends in Iloilo City, incorporating graphical visualizations such as heatmaps, trends, and historical graphs. The study explored the application of artificial intelligence (AI) in dengue prediction, utilizing deep learning models. The performance of the Long Short-Term Memory (LSTM) model was compared with traditional statistical methods, including non-seasonal and seasonal Autoregressive Integrated Moving Average (ARIMA) models and the Kalman Filter. Evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) were used to identify the most effective model for integration into the system. Forecasting was based on climate variables such as temperature, rainfall, relative humidity, and previous monthly case counts. The LSTM model emerged as the best performer with an RMSE of 16.15, demonstrating its suitability for time-series predictions, while the Kalman Filter showed the poorest performance with an RMSE of 38.40. By integrating predictive analytics with real-time data visualization, the proposed system aims to support public health agencies, such as the Department of Health (DOH), by providing actionable insights for proactive intervention strategies. This AI-driven solution enhances traditional outbreak reporting systems by enabling timely, data-informed decisions to mitigate the impact of dengue in the region.

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

156 This study explores the monitoring and forecasting of dengue outbreaks by an-
157 alyzing key factors such as temperature, relative humidity, and historical dengue
158 cases, using different models. The findings aim to provide an advanced, AI-driven
159 alternative for dengue prevention and control, targeting agencies like the Depart-
160 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
161 in Iloilo City, this research aspires to improve outbreak responses through cutting-
162 edge technology rather than traditional reporting methods.

163 1.2 Problem Statement

164 Dengue remains a critical public health challenge worldwide, with cases increasing
165 due to the easing of COVID-19 restrictions and heightened global mobility. While
166 a temporary decline in cases was observed during the pandemic (2020–2022) due
167 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
168 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
169 regions like the Philippines, the threat is particularly severe. In Iloilo City and
170 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
171 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
172 pital beds occupied by dengue patients, highlighting the urgent need for effective
173 predictive tools. The lack of a reliable system to monitor and forecast dengue
174 outbreaks contributes to delayed interventions, exacerbating public health risks
175 and healthcare burdens in the region.

176 1.3 Research Objectives

177 1.3.1 General Objective

178 This study aims to develop an AI-based dengue forecasting and monitoring system
179 for Iloilo City and Province. The researchers will train and compare multiple deep
180 learning models to predict dengue case trends based on climate data and historical
181 dengue cases to help public health officials in possible dengue case outbreaks.

182 1.3.2 Specific Objectives

183 Specifically, this study aims to:

- 184 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
185 (including temperature, rainfall, wind, and humidity) from online sources.
186 Combine and aggregate these data into a unified dataset to facilitate com-
187 prehensive dengue case forecasting.
- 188 2. Evaluate deep learning models for predicting dengue cases using metrics
189 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
190 and Mean Squared Error (MSE). Compare the performance of these models
191 to determine the most accurate forecasting approach.
- 192 3. Develop a web-based analytics dashboard that integrates a predictive model
193 and provides data management system for dengue cases in Iloilo City and
194 the Province.
- 195 4. Assess the usability and effectiveness of the analytics dashboard through
196 structured feedback and surveys involving health professionals and policy-
197 makers.

198 1.4 Scope and Limitations of the Research

199 This study aims to gather dengue data from the Iloilo Provincial Health Office
200 and climate data from online sources such as PAGASA or weatherandclimate.com.
201 These data will be preprocessed, cleaned, and combined into a unified dataset to
202 facilitate comprehensive dengue case forecasting. However, the study is limited by
203 the availability and completeness of historical data. Inconsistent or missing data
204 points may introduce biases and reduce the quality of predictions. Furthermore,
205 the granularity of the data will be in a weekly format.

206 To evaluate deep learning models for predicting dengue cases, the study will
207 train and compare the performance of various models, using metrics like Mean
208 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
209 aim to provide accurate forecasts, their performance is heavily influenced by the
210 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
211 predictions. Additionally, the models cannot fully account for external factors
212 such as public health interventions or socio-economic conditions which may impact
213 dengue transmission dynamics.

214 The study also involves developing a web-based analytics dashboard that in-
215 tegrates predictive models and provides a data management system for dengue
216 cases in Iloilo City and the Province. This dashboard will offer public health
217 officials an interactive interface to visualize dengue trends, input new data, and

218 identify risk areas. However, its usability depends on feedback from stakeholders,
219 which may vary based on their familiarity with analytics tools. Moreover, exter-
220 nal factors such as limited internet connectivity or device availability in remote
221 areas may affect the system’s adoption and effectiveness. While the dashboard
222 provides valuable insights, it cannot incorporate all factors influencing dengue
223 transmission, emphasizing the need for ongoing validation and refinement.

224 1.5 Significance of the Research

225 This study’s development of an AI-based dengue forecasting and monitoring sys-
226 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 227 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
228 and local health units in Iloilo City and Province stand to benefit greatly
229 from the system. With dengue predictions, we can help these agencies opti-
230 mize their response strategies and implement targeted prevention measures
231 in high-risk areas before cases escalate.
- 232 • **Local Government Units (LGUs):** LGUs can use the system to support
233 their disaster management and health initiatives by proactively addressing
234 dengue outbreaks. The predictive insights allow for more efficient planning
235 and resource deployment in barangays and communities most vulnerable to
236 outbreaks, improving overall public health outcomes.
- 237 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
238 occupancy rates during dengue season will benefit from early outbreak fore-
239 casts that can help in managing patient inflow and ensuring adequate hos-
240 pital capacity.
- 241 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
242 able insights for researchers studying infectious disease patterns and policy-
243 makers focused on strengthening the national AI Roadmap. The system’s
244 data can support broader initiatives for sustainable health infrastructure
245 and inform policy decisions on resource allocation for dengue control.
- 246 • **Community Members:** By reducing the frequency and severity of outbreaks,
247 this study ultimately benefits the community at large. This allows for timely

248 awareness campaigns and community engagement initiatives, empowering
249 residents with knowledge and preventative measures to protect themselves
250 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

274 public health concern. Studies suggest that outbreak thresholds should be context-
 275 specific, given the variability in transmission dynamics across different locations
 276 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
 277 Channel often base thresholds on 2 standard deviations (SD) above the mean
 278 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
 279 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
 280 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
 281 significantly across regions and time, making them inconsistent and incomparable.

282 From the studies above, this research implements an outbreak definition basing
 283 the threshold on 2 standard deviations (SD) above the mean number of historic
 284 dengue cases. It is important to note that for future outbreak definitions, addi-
 285 tional local context like available hospital space etc., must be taken into account
 286 for a more effective outbreak definition.

287 **2.3 Existing System: RabDash DC**

288 RabDash, developed by the University of the Philippines Mindanao, is a web-
 289 based dashboard for rabies data analytics. It combines predictive modeling with
 290 genomic data, enabling local health authorities to optimize interventions and al-
 291 locate resources more effectively. RabDash’s modules include trend visualization,
 292 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
 293 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

294 For DengueWatch, RabDash serves as a strong inspiration, particularly in
 295 its monitoring, historical trend visualization, and forecasting capabilities. These
 296 features align well with the needs of dengue control efforts, providing real-time
 297 insights into outbreak trends and enabling more effective, data-driven decision-
 298 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
 299 breaks similarly require time-series forecasting models. By using LSTM, RabDash
 300 effectively models trends in outbreak data, which provides a framework for adapt-
 301 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
 302 form traditional methods, such as ARIMA and MLP, in handling the complexities
 303 of time-dependent epidemiological data (Ligue & Ligue, 2022).

304 2.4 Deep Learning

305 The study of (Ligue & Ligue, 2022) highlights how data-driven models can help
306 predict dengue outbreaks. The authors compared traditional statistical meth-
307 ods, such as non-seasonal and seasonal autoregressive integrated moving average
308 (ARIMA), and traditional feed-forward network approach using a multilayer per-
309 ceptron (MLP) model with a deep learning approach using the long short-term
310 memory (LSTM) architecture in their prediction model. They found that the
311 LSTM model performs better in terms of accuracy. The LSTM model achieved a
312 much lower root mean square error (RMSE) compared to both MLP and ARIMA
313 models, proving its ability to capture complex patterns in time-series data (Ligue
314 & Ligue, 2022). This superior performance is attributed to LSTM’s capacity
315 to capture complex, time-dependent relationships within the data, such as those
316 between temperature, rainfall, humidity, and mosquito populations, all of which
317 contribute to dengue incidence (Ligue & Ligue, 2022).

318 2.5 Kalman Filter

319 The Kalman Filter is another powerful tool for time-series forecasting that can be
320 integrated into our analysis. It provides a recursive solution to estimating the state
321 of a linear dynamic system from a series of noisy measurements. Its application
322 in epidemiological modeling can enhance prediction accuracy by accounting for
323 uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters
324 are effective in predicting infectious disease outbreaks by refining estimates based
325 on observed data. A study published in *Frontiers in Physics* utilized the Kalman
326 filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman
327 filter effectively tracked the progression of deaths and cases, providing critical in-
328 sights for public health decision-making (Ahmadini et al., 2021). Another research
329 article in *PLOS ONE* focused on tracking the effective reproduction number (R_t)
330 of COVID-19 using a Kalman filter. This method estimated the growth rate of
331 new infections from noisy data, demonstrating that the Kalman filter could main-
332 tain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli,
333 Bullano, Kucinskas, & Rondón-Moreno, 2021).

334 Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM
335 models using our own collected dengue case data along with weather data to
336 identify the most effective model for real-time forecasting.

2.6 Weather Data

The relationship between weather patterns and mosquito-borne diseases is inherently nonlinear, meaning that fluctuations in disease cases do not respond proportionally to changes in climate variables (Colón-González, Fezzi, Lake, & Hunter, 2013). Weather data, such as minimum temperature and accumulated rainfall, are strongly linked to dengue case fluctuations, with effects observed after several weeks due to mosquito breeding and virus incubation cycles. Integrating these lagged weather effects into predictive models can improve early warning systems for dengue control (Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests that weather-based forecasting models using variables like mean temperature and cumulative rainfall can provide early warnings of dengue outbreaks with high sensitivity and specificity, enabling predictions up to 16 weeks in advance (Hii, Zhu, Ng, Ng, & Rocklöv, 2012).

We will utilize weather data, including variables such as temperature, rainfall, and humidity, as inputs for our dengue forecasting model. Given the strong, nonlinear relationship between climate patterns and dengue incidence, these weather variables, along with their lagged effects, are essential for enhancing prediction accuracy and providing timely early warnings for dengue outbreaks.

2.7 Chapter Summary

This chapter reviewed key literature relevant to our study, focusing on existing systems, predictive modeling techniques and the role of weather data in forecasting dengue outbreaks. We examined systems like RabDash DC, which integrates predictive modeling with real-time data to inform public health decisions, providing a foundational structure for our Dengue Watch System. Additionally, deep learning approaches, particularly Long Short-Term Memory (LSTM) networks, were highlighted for their effectiveness in time-series forecasting, while alternative methods such as ARIMA and Kalman Filters were considered for their ability to model complex temporal patterns and handle noisy data.

The literature further underscores the significance of weather variables—such as temperature and rainfall—in forecasting dengue cases. Studies demonstrate that these variables contribute to accurate outbreak prediction models. Leveraging these insights, our study will incorporate both weather data and historical dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

3.1 Research Activities

3.1.1 Gather Dengue Data and Climate Data to Create a Complete Dataset for Forecasting

Acquisition of Dengue Case Data

The historical dengue case dataset used in this study was obtained from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD) via Freedom of Information (FOI) requests. The decision to use weekly intervals was driven by the need for precision and timeliness in capturing fluctuations in dengue cases and weather conditions. Dengue transmission is influenced by short-term changes in weather variables such as rainfall and temperature, which impact mosquito breeding and virus transmission cycles. A weekly granularity allowed the model to better capture these short-term trends, enabling more accurate predictions and responsive public health interventions.

Moreover, using a weekly interval provided more data points for training the models compared to a monthly format. This is particularly critical in time series modeling, where larger datasets help improve the robustness of the model and its ability to generalize to new data. Also, the collection of weather data was done by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall, temperature, and humidity) from Weather Underground (wunderground.com).

Data Fields

- **Time.** Represents the specific year and week corresponding to each entry in the dataset.
- **Rainfall.** Denotes the observed average rainfall, measured in millimeters, for a specific week.
- **Humidity.** Refers to the observed average relative humidity, expressed as a percentage, for a specific week.
- **Max Temperature.** Represents the observed maximum temperature, measured in degrees Celsius, for a specific week.
- **Average Temperature.** Represents the observed average temperature, measured in degrees Celsius, for a specific week.

- 413 • **Min Temperature.** Represents the observed minimum temperature, mea-
414 sured in degrees Celsius, for a specific week.
- 415 • **Wind.** Represents the observed wind speed, measured in miles per hour
416 (mph), for a specific week.
- 417 • **Cases.** Refers to the number of reported dengue cases during a specific
418 week.

419 **Data Integration and Preprocessing**

420 The dengue case data was integrated with the weather data to create a com-
421 prehensive dataset, aligning the data based on corresponding timeframes. The
422 dataset underwent a cleaning process to address any missing values, outliers, and
423 inconsistencies to ensure its accuracy and reliability. To ensure that all features
424 and the target variable were on the same scale, a MinMaxScaler was applied to
425 normalize both the input features (climate data) and the target variable (dengue
426 cases).

427 **Exploratory Data Analysis (EDA)**

- 428 • Analyzed trends, seasonality, and correlations between dengue cases and
429 weather factors.
- 430 • Created visualizations like time series plots and scatterplots to highlight
431 relationships and patterns in the data.

432 **Outbreak Detection**

433 To detect outbreaks, we computed the outbreak threshold value of dengue cases
434 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

435 where μ is the historical mean and σ is the standard deviation.

436 3.1.2 Develop and Evaluate Deep Learning Models for 437 Dengue Case Forecasting

438 The deep learning models were developed and trained to forecast weekly dengue
439 cases using historical weather data (rainfall, temperature, wind, and humidity)
440 and dengue case counts. The dataset was normalized and divided into training and
441 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
442 for preparing and training the model are outlined below.

443 Data Preprocessing

444 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
445 ture, wind, humidity) and dengue case counts. The "Time" column was converted
446 to a datetime format to ensure proper temporal indexing. To standardize the data
447 for training, MinMaxScaler was employed, normalizing the feature values and tar-
448 get variable to a range of 0 to 1. This step ensured that the models could efficiently
449 process the data without being biased by feature scaling differences.

450 LSTM Model

451 The dataset was split into training and test sets to evaluate the model's perfor-
452 mance and generalizability:

- 453 • **Training Set:** 80% of the data (572 sequences) was used for model training,
454 enabling the LSTM to learn underlying patterns in historical dengue case
455 trends and their relationship with weather variables.
- 456 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
457 testing

458 To prepare the data for LSTM, a sliding window approach was utilized. Se-
459 quences of weeks of normalized features were constructed as input, while the
460 dengue case count for the subsequent week was set as the target variable. This
461 approach ensured that the model leveraged temporal dependencies in the data for
462 forecasting. To enhance the performance of the LSTM model in predicting dengue
463 cases, Bayesian Optimization was employed using the Keras Tuner library. The
464 tuning process aimed to minimize the validation loss (mean squared error) by
465 adjusting key model hyper-parameters. The search space is summarized below:

466 **LSTM units:**

- 467 • min value: 32
- 468 • max value: 128
- 469 • step: 16
- 470 • sampling: linear

471 **Learning Rate:**

- 472 • min value: 0.0001
- 473 • max value: 0.01
- 474 • step: None
- 475 • sampling: log

476 The tuner was instantiated with:

- 477 • **max trials = 10:** Limiting the search to 10 different configurations
- 478 • **executions per trial = 3:** Running each configuration thrice to reduce
479 variance
- 480 • **validation split = 0.2:** Reserving 20% of the training data for validation

481 The hyperparameter tuning was conducted for three different window sizes of
482 data: 5, 10, and 20. This allows the model to have the optimal hyperparameters
483 used for each window size. Training was conducted over 100 epochs with early
484 stopping to prevent overfitting while maintaining computational efficiency. A
485 batch size of 1 was used, enabling the model to process individual sequences,
486 which is suitable for smaller datasets but results in longer training times. The
487 Adam optimizer, known for its adaptive learning capabilities and stability was
488 employed.

489 To validate the effectiveness of the model, cross-validation was implemented.
490 However, standard k-fold cross-validation randomly shuffles the data, which isn't
491 suitable for time series since the order of observations is important. To address
492 this, a time series-specific cross-validation strategy was used with TimeSeriesS-
493 plit from the scikit-learn library. This method creates multiple train-test splits

494 where each training set expands over time and each test set follows sequentially.
495 This approach preserves the temporal structure of the data while helping reduce
496 overfitting by validating the model across different time segments.

497 After training, predictions on both the training and test datasets were rescaled
498 to their original scale using the inverse transformation of MinMaxScaler. Model
499 performance was evaluated using the mean squared error (MSE), root mean
500 squared error (RMSE) and mean absolute error (MAE).

501 **ARIMA**

502 The ARIMA model was utilized to forecast weekly dengue cases, leveraging histor-
503 ical weather data—including rainfall, maximum temperature, and humidity—as
504 exogenous variables alongside historical dengue case counts as the primary depen-
505 dent variable. The dataset was partitioned into training (80%) and testing (20%)
506 sets while maintaining temporal consistency.

507 To identify the optimal ARIMA configuration, a comprehensive grid search
508 was performed across the following parameter ranges:

- 509 • Autoregressive order (p): 0 to 3
- 510 • Differencing order (d): 0 to 2
- 511 • Moving average order (q): 0 to 3

512 Each combination of (p,d,q) was used to fit an ARIMA model, and perfor-
513 mance was evaluated based on the mean squared error (MSE) between the pre-
514 dicted and actual dengue cases on the test set. The parameter set that achieved
515 the lowest MSE was selected as the final model configuration.

516 Following model selection, the best-fit ARIMA model was retrained on the
517 training set and subsequently used to forecast dengue cases for the test period.
518 The predictions were assigned to the **PredictedCases** column in the test dataset.
519 Model performance was further assessed using key evaluation metrics, including
520 MSE, root mean squared error (RMSE), and mean absolute error (MAE). Visual
521 comparisons between actual and predicted dengue cases were produced through
522 line plots to better illustrate the model’s forecasting accuracy.

523 Seasonal ARIMA (SARIMA)

524 The SARIMA modeling process began with data preprocessing, which included
525 handling missing values through interpolation or imputation, and standardizing
526 features to ensure stable model training. The dataset was then split into training
527 and testing sets in an 80:20 ratio, preserving the temporal order of observations.
528 Seasonality analysis was conducted using time series decomposition and autocor-
529 relation plots, which revealed a periodicity of 52 weeks—justifying the adoption
530 of a seasonal model. To fine-tune the model, a grid search was performed over a
531 range of SARIMA parameters $(p,d,q)(P,D,Q)[S]$, while stationarity was validated
532 using the Augmented Dickey-Fuller (ADF) test. The model was then trained
533 on the dataset using rainfall, temperature, and humidity as exogenous variables,
534 with convergence ensured by setting a maximum number of iterations. Residual
535 diagnostics were used to confirm that residuals were uncorrelated, indicating a
536 good model fit. For evaluation, forecasts were compared against actual values,
537 and results were visualized with line plots. Finally, to validate the model’s gener-
538 alizability across different time periods, Time Series Cross-Validation with three
539 folds was applied. This allowed assessment of the model’s performance on multi-
540 ple time segments, providing insights into its robustness in real-world forecasting
541 scenarios.

542 Kalman Filter:

- 543 • Input Variables: The target variable (Cases) was modeled using three re-
544 gressors: rainfall, max temperature, and humidity.
- 545 • Training and Testing Split: The dataset was split into 80% training and
546 20% testing to evaluate model performance.
- 547 • Observation Matrix: The Kalman Filter requires an observation matrix,
548 which was constructed by adding an intercept (column of ones) to the re-
549 gressors.

550 The Kalman Filter’s Expectation-Maximization (EM) method was employed
551 for training, iteratively estimating model parameters over 10 iterations. After
552 training, the smoothing method was used to compute the refined state estimates
553 across the training data. Observation matrices for the test data were constructed
554 in the same manner as for the training set, ensuring compatibility with the learned
555 model parameters. On the test data, the Kalman Filter applied these parameters
556 to predict and correct the estimated dengue cases, providing more stable and
557 accurate forecasts compared to direct regression models. Additionally, a hybrid

558 Kalman Filter–LSTM (KF-LSTM) model was developed to combine the strengths
559 of both approaches. In this setup, the LSTM model was first used to predict
560 dengue cases based on historical data and weather features. The Kalman Filter
561 was then applied as a post-processing step to the LSTM predictions, smoothing
562 out noise and correcting potential errors.

563 **3.1.3 Integrate the Predictive Model into a Web-Based** 564 **Data Analytics Dashboard**

565 **Dashboard Design and Development**

- 566 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 567 – Interactive visualizations of yearly dengue case trends.
 - 568 – Data input and update forms for dengue and weather data.
 - 569 – Map display of dengue cases in each district in Iloilo City

570 **Model Integration and Deployment**

- 571 • Deploy the best-performing model within the dashboard as a backend service
572 to enable real-time or periodic forecasting.

573 **3.1.4 System Development Framework**

574 The Agile Model is the birthchild of both iterative and incremental approaches
575 in Software Engineering. It aims to be flexible and effective at the same time by
576 being adaptable to change. It's also important to note that small teams looking
577 to construct and develop projects quickly can benefit from this kind of method-
578 ology. As the Agile Method focuses on continuous testing, quality assurance is a
579 guarantee since bugs and errors are quickly identified and patched.

580 **Design and Development**

581 After brainstorming and researching the most appropriate type of application to
582 accommodate both the prospected users and the proposed solutions, the team
583 has decided to proceed with a web application. Given the time constraints and
584 available resources, it has been decided that the said means is the most pragmatic

585 and practical move. The next step is to select modern and stable frameworks
 586 that align with the fundamental ideas learned by the researchers in the university.
 587 The template obtained from WVCHD and Iloilo Provincial Epidemiology and
 588 Surveillance Unit was meticulously analyzed to create use cases and develop a
 589 preliminary well-structured database that adheres to the requirements needed
 590 to produce a quality application. The said use cases serve as the basis of general
 591 features. Part by part, these are converted into code, and with the help of selected
 592 libraries and packages, it resulted in the desired outcome that may still modified
 593 and extended to achieve scalability.

594 Testing and Integration

Figure 3.2: Testing Process for DengueWatch

595 Implementing testing is important to validate the system's performance and ef-
 596 ficacy. Thus a series of tests were conducted to identify and resolve bugs during
 597 the developmental phase. Each feature was rigorously tested to ensure quality as-
 598 surance, with particular emphasis on prerequisite features, as development cannot
 599 progress properly if these fail. Because of this, integration between each feature

600 serves as a pillar for a cohesive user experience. Since dengue reports include
601 confidential information, anonymized historical dengue reports were used to train
602 the model and create the foundational architecture of the system. By using func-
603 tional tests, data validation and visualization can be ensured for further continual
604 improvements. Security testing is also important as it is needed to safeguard
605 confidential information when the system is deployed. It includes proper authen-
606 tication, permission views, and mitigating common injection attacks. Finally, a
607 user acceptance test from the prospected users, in this case, doctors, nurses, and
608 other health workers is crucial to assess its performance and user experience. It
609 enables the developers to confirm if the system meets the needs of the problem.

610 **3.2 Development Tools**

611 **3.2.1 Software**

612 **Github**

613 GitHub is a cloud-based platform that tracks file changes using Git, an open-
614 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
615 used in the project to store the application’s source code, manage the system’s
616 source version control, and serve as a repository for the Latex files used in the
617 actual research.

618 **Visual Studio Code**

619 Visual Studio Code is a free, lightweight, and cross-platform source code editor
620 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
621 this project’s programming and scripting languages, it was chosen as the primary
622 source code editor.

623 **Django**

624 Django is a free and open-sourced Python-based web framework that offers an
625 abstraction to develop and maintain a secure web application. As this research
626 aims to create a well-developed and maintainable application, it is in the best
627 interest to follow an architectural pattern that developers and contributors in the

628 future can understand. Since Django adheres to Model-View-Template (MVT)
629 that promotes a clean codebase by separating data models, business logic, and
630 presentation layers, it became the primary candidate for the application’s back-
631 bone.

632 **Next.js**

633 A report by Statista (2024) claims that React is the most popular front-end frame-
634 work among web developers. However, React has limitations that can be a nui-
635 sance in rapid software development, which includes routing and performance op-
636 timizations. This is where Next.js comes in—a framework built on top of React.
637 It offers solutions for React’s deficiency, making it a rising star in the framework
638 race.

639 **Postman**

640 As the application heavily relies on the Application Programming Interface (API)
641 being thrown by the backend, it is a must to use a development tool that facilitates
642 the development and testing of the API. Postman is a freemium API platform
643 that offers a user-friendly interface to create and manage API requests (*What is*
644 *Postman? Postman API Platform*, n.d.).

645 **3.2.2 Hardware**

646 The web application is continuously being developed on laptop computers with
647 minimum specifications of an 11th-generation Intel i5 CPU and 16 gigabytes of
648 RAM.

649 **3.2.3 Packages**

650 **Django REST Framework**

651 Django Rest Framework (DRF) is a third-party package for Django that provides a
652 comprehensive suite of features to simplify the development of robust and scalable
653 Web APIs (Christie, n.d.). These services include Serialization, Authentication
654 and Permissions, Viewsets and Routers, and a browsable API .

655 Leaflet

656 One of the features of the web application is the ability to map the number
657 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
658 most importantly, stable JavaScript package that can do the job. With its ultra-
659 lightweight size, it offers a comprehensive set of features that does not trade
660 off performance and usability (*Leaflet — an open-source JavaScript library for*
661 *interactive maps*, n.d.).

662 Chart.js

663 Another feature of the application is to provide users with informative, approach-
664 able data storytelling that is easy for everyone to understand. The transformation
665 of pure data points and statistics into figures such as charts is a big factor. Thus,
666 there is a need for a package that can handle this feature without compromising
667 the performance of the application. Chart.js is a free and open-source JavaScript
668 package that is made to meet this criteria as it supports various types of charts
669 (*Chart.js*, n.d.).

670 Tailwind CSS

671 Using plain CSS in production-quality applications can be counterproductive.
672 Therefore, CSS frameworks were developed to promote consistency and accelerate
673 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
674 which offers low-level utility classes that can be applied directly to each HTML
675 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
676 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
677 project, using this framework is a wise choice due to its stability and popularity
678 among developers.

679 Shadcn

680 Shadcn offers a collection of open-source UI boilerplate components that can be
681 directly copied and pasted into one's project. With the flexibility of the provided
682 components, Shadcn allows developers to have full control over customization and
683 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
684 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

685 **Zod**

686 Data validation is integral in this web application since it will handle crucial data
687 that will be used for analytical inferences and observations. Since Zod is primarily
688 used for validating and parsing data, it ensures proper communication between
689 the client and the server (Zod, n.d.).

690 3.3 Application Requirements

691 3.3.1 Backend Requirements

692 Database Structure Design

693 Determining how data flows and how it would be structured is crucial in creating
 694 the system as it defines how extendible and flexible it would be for future features
 695 and updates. Thus, creating a comprehensive map of data ensures proper nor-
 696 malization that eliminates data redundancy and improves data integrity. Figure
 697 3.3 depicts the designed database schema that showcases the relationship between
 698 the application's entities.

Figure 3.3: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

699 3.3.2 User Interface Requirements

700 Disease Reporting Unit Admin Interface

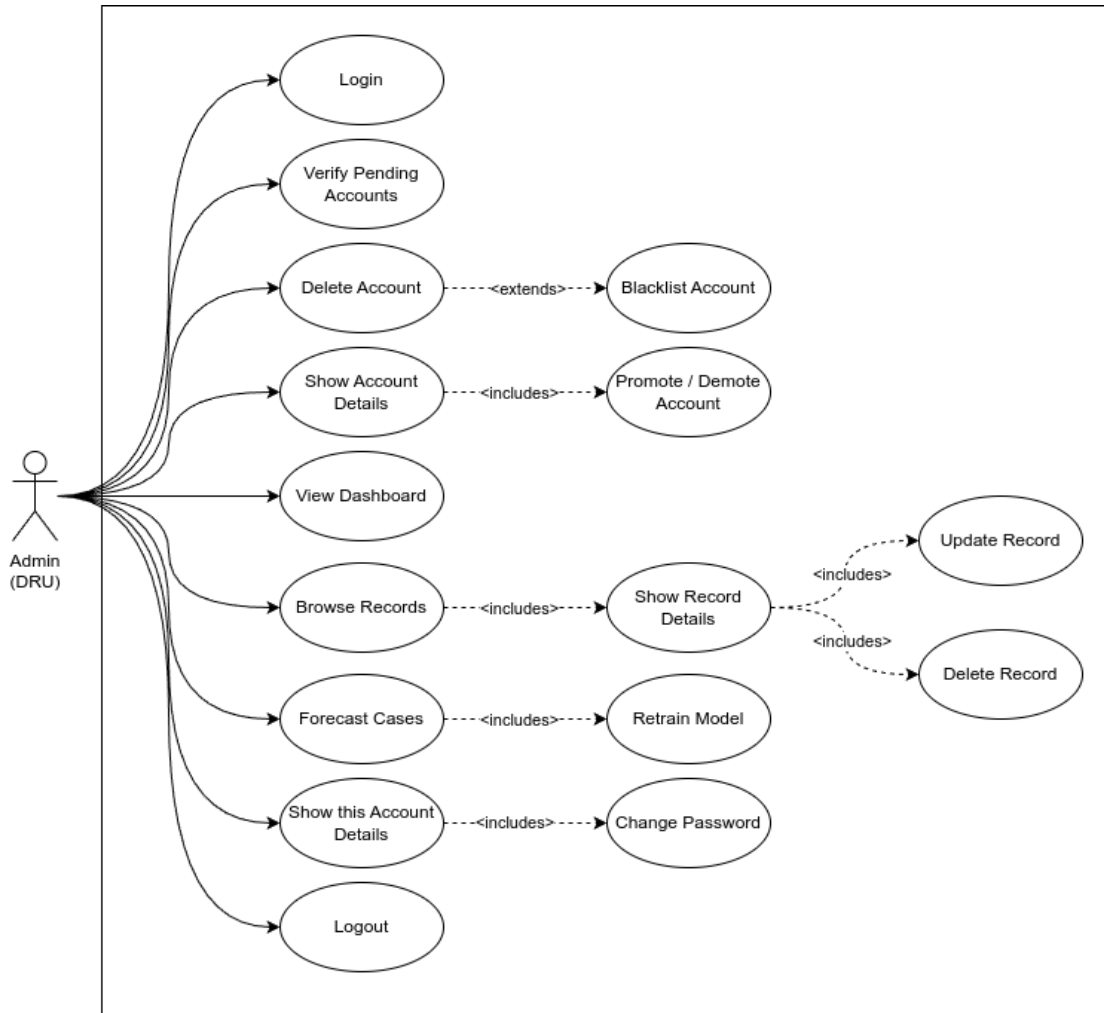

Figure 3.4: Use Case Diagram for DRU Admin

701 Surveillance Unit Admin Interface

702 Figure 3.4 shows the actions an admin for a specific Disease Reporting Unit (DRU)
 703 can take in the application. These include managing accounts, browsing records,
 704 and forecasting and retraining all the consolidated data under the unit. To protect
 705 the integrity of data, encoders that register to a DRU must first be verified by
 706 these users, and then the encoder's account can only be authorized to use the

707 application.

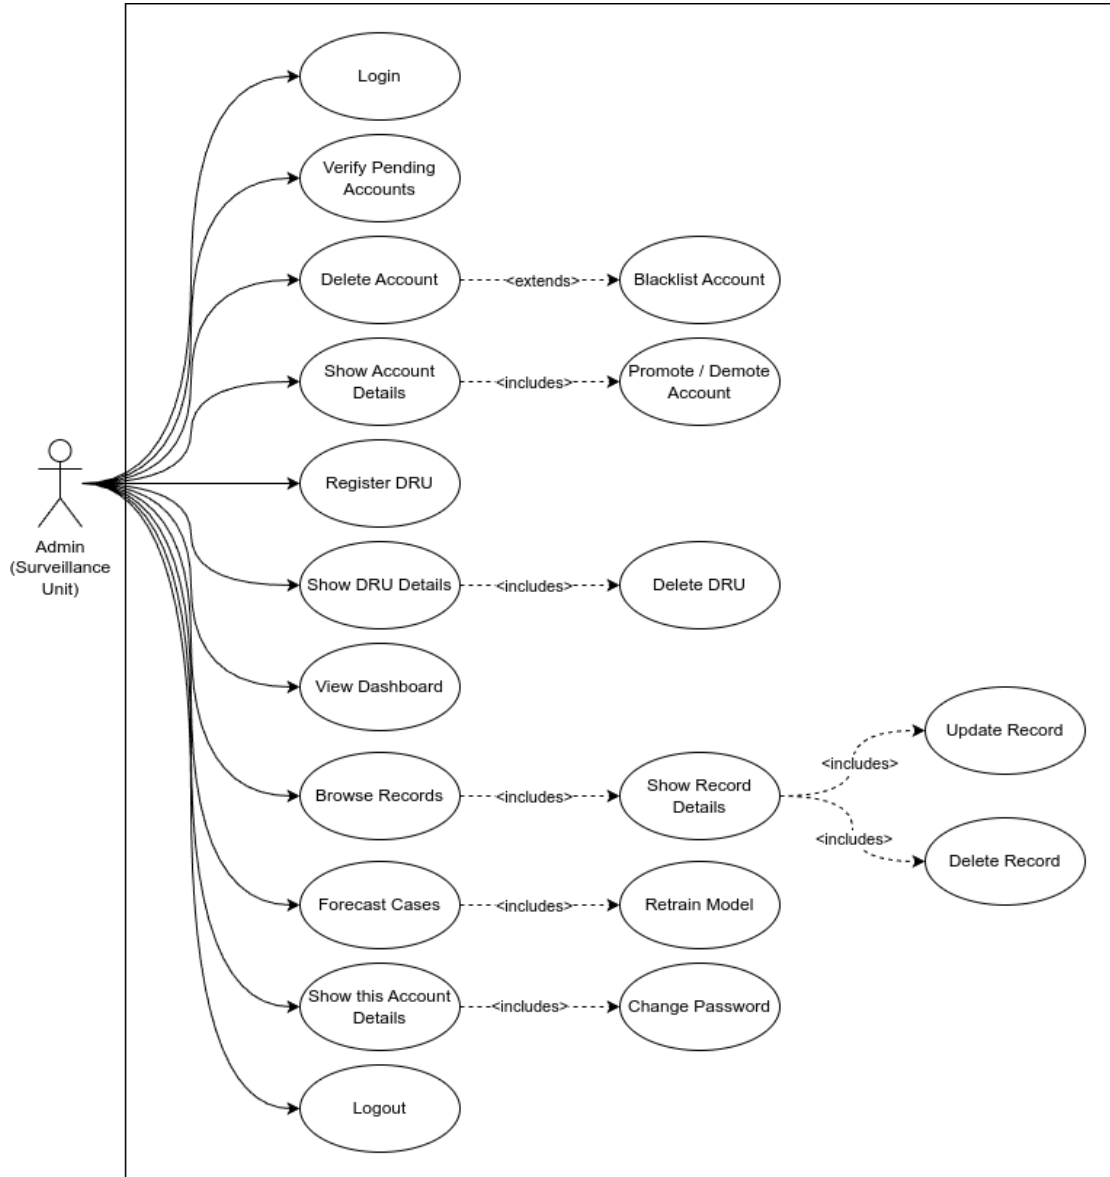

Figure 3.5: Use Case Diagram for Surveillance Unit Admin

708 While the previous use case focuses on hospitals, clinics, and other reporting
709 units, the use case presented in Figure 3.5 has a one-step higher authorization as
710 it manages these DRUs. It has the same features as the DRU admin but with
711 extra management of the DRUs under a specific surveillance unit. At this point,
712 only the authorized surveillance unit administrator can register and create a DRU
713 to uphold transparency and accountability.

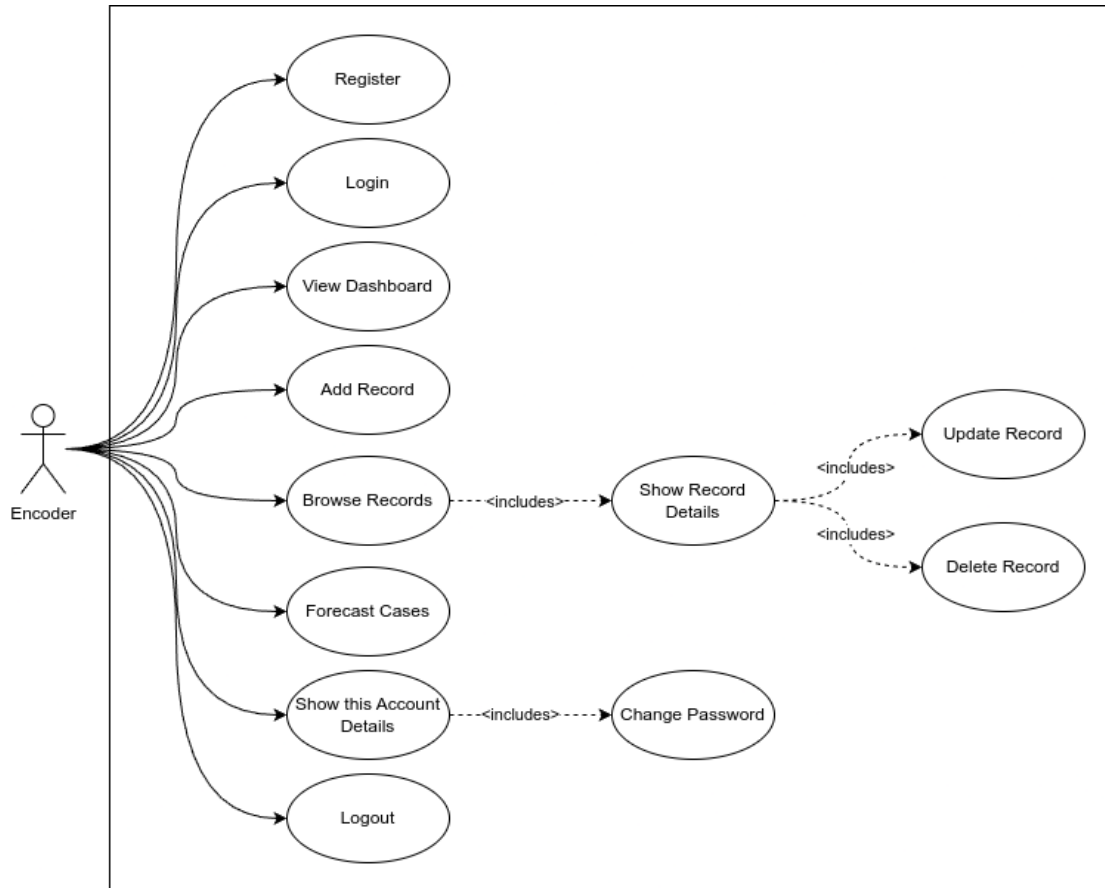

Figure 3.6: Use Case Diagram for Encoder

715 Figure 3.6, on the other hand, illustrates the use cases for the system's primary
 716 users. These users can register but must wait for further verification to access the
 717 application. Similar to the previous interfaces, encoders can browse and manage
 718 records, as well as forecast the consolidated cases under a specific surveillance or
 719 disease reporting unit, but they are not allowed to retrain the model. Lastly, they
 720 are the only type of user that can file and create dengue cases by filling out a form
 721 with the required details.

722 3.3.3 Security and Validation Requirements

723 Password Encryption

724 Storing passwords as plain text in the database is a disgrace and a mortal sin in
725 production. It is important to implement precautionary methods such as hashing
726 and salting, followed by encryption with a strong algorithm, to prevent bad actors
727 from using the accounts for malicious transactions. By default, Django generates
728 a unique random salt for each password and encrypts it with Password-Based Key
729 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
730 techniques ensures that in the event of a data breach, cracking these passwords
731 would be time-consuming and useless for the attackers.

732 Authentication

733 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
734 the mechanism operates in a stateless manner, tokens are served only after a
735 successful login, eliminating the need for the server to keep a record of the token,
736 which is vulnerable to session hijacking. In addition, these tokens are signed with
737 a secret key, ensuring they have not been tampered with.

738 Data Validation

739 Both the backend and frontend should validate the input from the user to preserve
740 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
741 from the user. By doing this, the user can only send proper requests to the server
742 which streamlines the total workflow. On the other hand, Django has also a built-
743 in validator that checks the data type and ensures that the input matches the
744 expected format on the server side. These validation processes ensure that only
745 valid and properly formatted data is accepted, which reduces the risk of errors
746 and ensures consistency across the web application.

747 3.4 Calendar of Activities

748 A Gantt chart showing the schedule of the activities is included below. Each
749 bullet represents approximately one week of activity.

Table 3.1: Timetable of Activities for 2024

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. Dengue Case Data: The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. Weather Data: Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

```
data.head()

768 4.2 Exploratory Data Analysis

769 From the summary above, the dataset consists of 720 weekly records with 8
770 columns:

- 771 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 772 • **Rainfall.** Weekly average rainfall (mm)
- 773 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
774 temperature data (C)
- 775 • **Wind.** Wind speed (m/s)
- 776 • **Humidity.** Weekly average humidity (%)
- 777 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks. To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

790 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 791 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

792

793 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 794 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 795 dengue cases. Notably, peak cases are observed during certain periods approx-
 796 imately 3 years, potentially aligning with specific climatic conditions such as
 797 increased rainfall or temperature changes. This underscores the importance of
 798 incorporating climate variables into the forecasting model.

799 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 800 and selected features, including rainfall, humidity, maximum temperature, aver-
 801 age temperature, minimum temperature, and wind speed. Among these, rainfall
 802 exhibits the highest positive correlation with dengue cases (correlation coefficient
 803 0.13), indicating that increased rainfall may contribute to higher cases counts.
 804 This aligns with existing studies suggesting that stagnant water from heavy rain-
 805 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 806 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 807 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 808 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 809 relationship than average and minimum temperature.

810 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 811 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

4.3 Outbreak Detection

To identify outbreaks, we calculated the outbreak threshold value using the historical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

where μ is the historical mean and σ is the standard deviation.

This result indicates that dengue cases exceeding 98 in Iloilo City can be considered an outbreak. However, it is important to note that this threshold serves only as a baseline. Additional parameters, such as the number of hospital beds available in the city, must be considered to compute a more effective threshold and develop an appropriate response strategy.

826 4.4 Model Training Results

827 The models were evaluated using three metrics: MSE, RMSE, and MAE. The
 828 table below provides a summary and comparative analysis of each model's results
 829 across these metrics, offering insights into the strengths and limitations of each
 830 forecasting technique for dengue case prediction in Iloilo City. The lower values
 831 of the three metrics indicate better forecasting performance. Table 4.1 shows that
 832 the models performed differently on testing data. LSTM outperformed the other
 833 models with the lowest RMSE, MSE, and MAE while the other three models had
 834 relatively higher values for the three metrics.

Method	LSTM	Seasonal ARIMA	ARIMA	Kalman Filter	KF-LSTM
Testing MSE	285.54	1261.20	1521.48	1474.82	785.35
Testing RMSE	16.90	34.45	39.00	38.40	25.56
Testing MAE	9.45	18.73	25.80	22.33	14.55
Best Parameters	Window Size: 5 Learning Rate: 0.01 Units: 64	(2,0,2)(0,1,1)	(1,2,2)	Observation Covariance: 10.0 Transition Covariance: $0.1 \times \text{Identity}$	Same as LSTM

Table 4.1: Comparison of different models for dengue prediction

835 4.4.1 LSTM Model

836 The LSTM model was tuned for the following parameters: learning rate and units.
 837 The hyperparameter tuning was conducted for each window size, finding the best
 838 parameters for each window size. Further evaluating which window size is most
 839 suitable for the prediction model, Table 4.2 shows the evaluation metrics for each
 window size used in the LSTM model training.

Window Size	MSE	RMSE	MAE	R ²
5	285.54	16.90	9.45	0.83
10	334.63	18.29	9.85	0.80
20	294.85	17.17	9.35	0.83

Table 4.2: Comparison of Window Sizes

840

841 The results indicate that a window size of 5 weeks provides the most accurate
 842 predictions, as evidenced by the lowest MSE and RMSE values. Furthermore, the
 843 R² score of 0.83 indicates that 83% of the variability in the target variable (cases)
 844 is explained by the independent variables (the inputs) in the model, making it a
 845 reliable configuration overall.

846 Figure 4.9 illustrates the model's performance in predicting dengue cases for
 847 each fold using a window size of 5. As shown in the plot, the training set progres-

848 sively increases with each fold, mimicking a real-world scenario where more data
849 becomes available over time for dengue prediction. Figure 4.10 demonstrates that
850 the predicted cases closely follow the trend of the actual cases, indicating that the
851 LSTM model successfully captures the underlying patterns in the data. It is also
852 evident that as the fold number increases and the training set grows, the accuracy
853 of the predictions on the test set improves. Despite the test data being unseen,
854 the model exhibits a strong ability to generalize, suggesting it effectively leverages
855 past observations to predict future trends.

Figure 4.9: Training Folds - Window Size 5

Figure 4.10: Testing Folds - Window Size 5

856 4.4.2 ARIMA Model

Figure 4.11: ARIMA Prediction Results for Test Set

857 The ARIMA model was developed to capture non-seasonal trends in the data.
 858 To determine the best model configuration, grid search was used to explore vari-
 859 ous combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**.
 860 The model was iteratively refined over **400 iterations** to ensure convergence to
 861 an optimal solution. Figure 4.11 illustrates the comparison between actual and
 862 predicted dengue cases in the test set. As shown in the plot, the ARIMA model
 863 struggled to capture the non-linear characteristics and abrupt spikes in the data.
 864 Consequently, it failed to accurately reflect the fluctuations and outbreak patterns
 865 seen in the actual case counts.

866 The model's performance was assessed using regression metrics to evaluate its
 867 forecasting capability. The ARIMA model yielded the following error metrics:

- 868 • **MSE (Mean Squared Error):** 1521.48
- 869 • **RMSE (Root Mean Squared Error):** 39.01
- 870 • **MAE (Mean Absolute Error):** 25.80

4.4.3 Seasonal ARIMA (SARIMA) Model

To address the limitations of the ARIMA model, a Seasonal ARIMA (SARIMA) model was developed to capture both non-seasonal and seasonal variations in the data.

Figure 4.12: Seasonal ARIMA Prediction Results for Test Set

This model incorporates seasonal parameters, which were tuned using grid search to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA, **400 iterations** were applied to ensure a robust fit. As shown in Figure 4.12, the SARIMA model demonstrates a notable improvement in performance. Unlike its non-seasonal counterpart, it effectively captures the general trend and aligns more closely with the peaks observed in the actual dengue cases, indicating its ability to model seasonal dynamics.

The model's performance was assessed using regression metrics to evaluate its forecasting capability. The SARIMA model yielded the following error metrics:

- **MSE:** 1109.69
- **RMSE:** 33.31

886

- **MAE: 18.09**

887

888

889

890

The lower error values, when compared to the ARIMA model, highlight the SARIMA model's superior capability in forecasting dengue cases. Its effectiveness in capturing seasonal patterns contributed to a more accurate representation of the actual cases.

891

892

893

894

895

896

After training the model, the SARIMA model was validated using the same Time Series Cross-Validation strategy employed in the LSTM model. Table 4.3 presents the performance metrics for each fold, as well as the average metrics across all folds. The average RMSE and MAE values were close to those obtained during the initial training phase, indicating that the SARIMA model performed consistently across different time segments.

Fold	MSE	RMSE	MAE
1	659.68	25.68	16.00
2	2127.49	46.12	21.30
3	996.43	31.56	18.89
Average	1261.20	34.45	18.73

Table 4.3: Comparison of SARIMA performance for each fold

897

4.4.4 Kalman Filter Model

898

899

900

901

902

903

904

905

Figure 4.13 shows the comparison between the actual dengue cases and the predicted values on the test set. As illustrated in the plot, the Kalman Filter model demonstrates a moderate ability to follow the general trend of the actual data. While it effectively captures some rising and falling patterns, it still struggles to accurately replicate the sharp peaks and extreme values found in the real case counts. This limitation is particularly noticeable during the large spikes in 2022 and 2024. The model's performance was evaluated using standard regression metrics. The results are as follows:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

Figure 4.13: Kalman Filter Prediction Results for Test Set

906 The Kalman Filter was then combined with the LSTM model in order to see
 907 improvements in its predictions. Table 4.4 shows the metrics across three folds
 908 using the same Time Series Cross Validation Strategy employed in the previous
 909 models to see how it performed on different time segments.

Fold	MSE	RMSE	MAE
1	113.59	10.66	6.42
2	752.51	27.43	12.11
3	1489.95	38.60	25.13
Average	785.35	25.56	14.55

Table 4.4: Comparison of KF-LSTM performance for each fold

910 As can be seen in the table above, the performance of the hybrid model demon-
 911 strated improvements in all metrics as compared to just using the Kalman Filter
 912 alone.

913 4.5 System Prototype

914 4.5.1 Guest Interface

915 The Guest Interface is intended for all visitors of the web application. It shows
916 the related statistics for dengue cases in a particular area and time. As the system
917 is still in its testing phase, the data converted into charts shown in Figure 4.14
918 are generated from Python's Faker library.

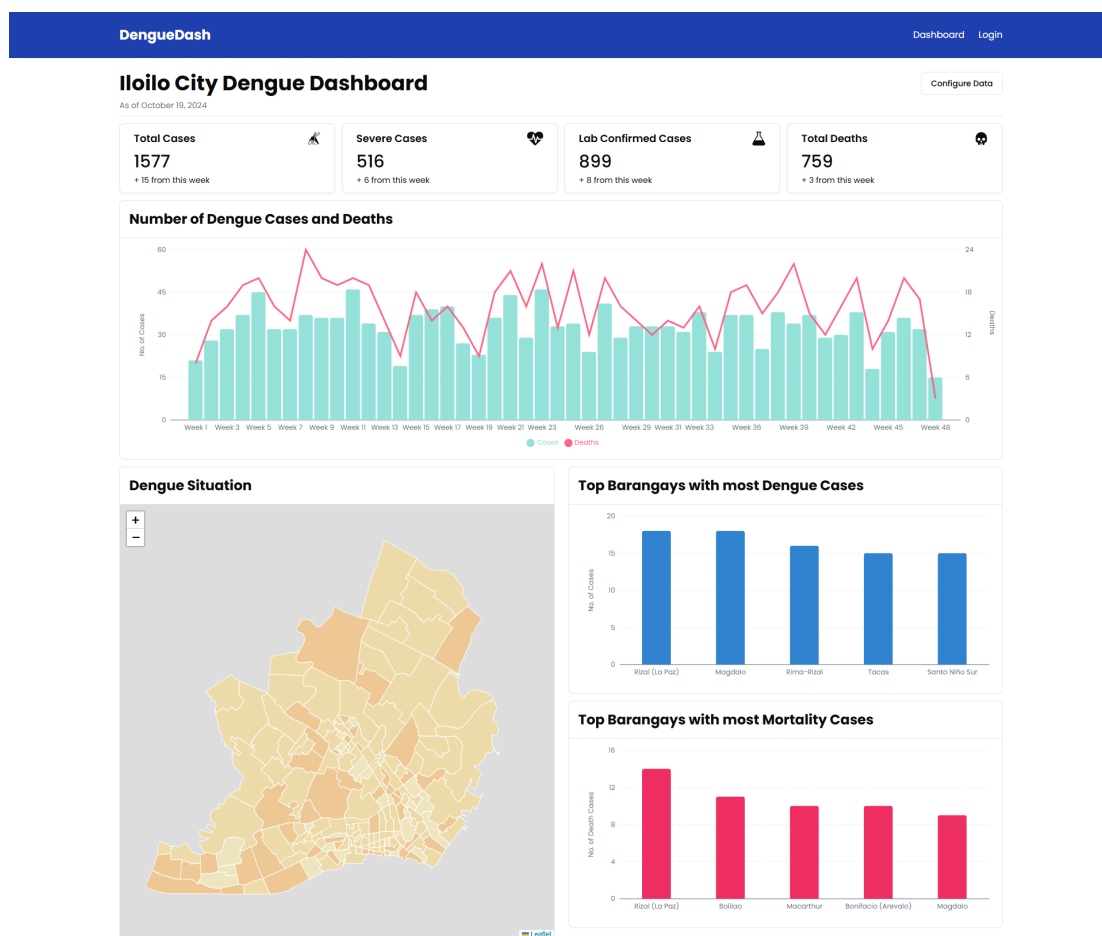

Figure 4.14: Dashboard for Guests

919 4.5.2 Personnel Interface

920 User Authentication, and Login

921 To protect the data's integrity in production, it has been decided that the registration process will not be visible. Instead, an admin must register a user using
922 a different interface. As of the moment, registering a user is done using API via
923 Postman. In the login process, the system implements HTTP-only cookies that
924 contains the JSON Web Tokens (JWT) to protect against XSS attacks. After
925 proper credentials have been provided, it will redirect to the user's home page.
926

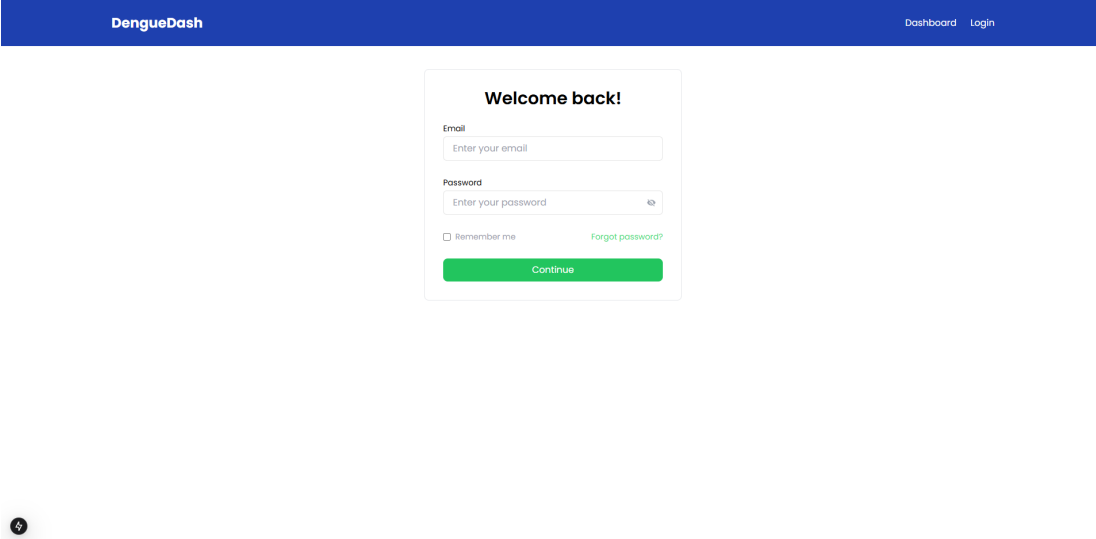

Figure 4.15: Login Page for Users

927 Encoder's View

928 Figures 4.16 and 4.17 show the digitized counterpart of the form obtained from the
929 Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to support
930 expandability for future features, some fields were modified to accommodate
931 more detailed input. It is worth noting that all of the included fields adhere to the
932 latest Philippine Integrated Disease and Surveillance Response (PIDSR) Dengue
933 Forms, which the referenced form was based on. By doing this, it is assumed
934 that the targeted users will have a familiarity when deployed on a national scale.
935 On a further note, the case form includes the patient's basic information, dengue
936 vaccination status, consultation details, laboratory results, and the outcome.

Figure 4.17: Second Part of Case Report Form

937 Once the data generated from the case report form is validated, it will be
 938 assigned as a new case and can be accessed through the Dengue Reports page, as
 939 shown in Figure 4.18. The said page displays basic information about the patient
 940 related to a specific case, including their name, address, date of consultation, and
 941 clinical and case classifications. It is also worth noting that it only shows cases
 942 the user is permitted to view. For example, in a local Disease Reporting Unit
 943 (DRU) setting, the user can only access records that came from the same DRU.
 944 On the other hand, in a consolidated surveillance unit such as a regional and
 945 provincial quarter, its users can view all the records that came from all the DRUs
 946 that report to them. Moving forward, Figure 4.19 shows the detailed case report
 947 of the patient on a particular consultation date.

The screenshot shows the DengueDash application interface. On the left is a sidebar menu with the following items: Analytics, Forms, Data Tables (expanded), Dengue Reports, Another Report, and Settings. The main content area is titled 'Building Your Application > Data Fetching' and displays a table of dengue reports. The table has columns for Case ID, Name, Barangay, City, Date Consulted, Clinical Classification, Case Classification, and Action. There are 12 rows of data, each with an 'Open' button in the Action column. At the bottom of the table, there is a pagination control showing '1' of 218 items.

Case ID	Name	Barangay	City	Date Consulted	Clinical Classification	Case Classification	Action
24010965	Robinson, Raymond Todd	Balabago	Iloilo City	2024-11-27	Severe dengue	Confirmed	Open
24010975	Harmon, Michelle Donna	Yulo-Arroyo	Iloilo City	2024-11-26	No warning signs	Suspect	Open
24010960	Thomas, Stephanie John	Calubihan	Iloilo City	2024-11-23	Severe dengue	Confirmed	Open
24010972	Cooper, Richard Rodney	PHHC Block 17	Iloilo City	2024-11-23	With warning signs	Probable	Open
