Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This research focused on developing a centralized system for monitoring and forecasting dengue trends in Iloilo City, incorporating graphical visualizations such as heatmaps, trends, and historical graphs. The study explored the application of artificial intelligence (AI) in dengue prediction, utilizing deep learning models. The performance of the Long Short-Term Memory (LSTM) model was compared with traditional statistical methods, including non-seasonal and seasonal Autoregressive Integrated Moving Average (ARIMA) models and the Kalman Filter. Evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) were used to identify the most effective model for integration into the system. Forecasting was based on climate variables such as temperature, rainfall, relative humidity, and previous monthly case counts. The LSTM model emerged as the best performer with an RMSE of 16.15, demonstrating its suitability for time-series predictions, while the Kalman Filter showed the poorest performance with an RMSE of 38.40. By integrating predictive analytics with real-time data visualization, the proposed system aims to support public health agencies, such as the Department of Health (DOH), by providing actionable insights for proactive intervention strategies. This AI-driven solution enhances traditional outbreak reporting systems by enabling timely, data-informed decisions to mitigate the impact of dengue in the region.

Keywords: ARIMA, artificial intelligence, dengue prediction, LSTM, Kalman Filter, deep learning, climate variables, public health, outbreak mitigation

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

158 This study explores the monitoring and forecasting of dengue outbreaks by an-
159 alyzing key factors such as temperature, relative humidity, and historical dengue
160 cases, using different models. The findings aim to provide an advanced, AI-driven
161 alternative for dengue prevention and control, targeting agencies like the Depart-
162 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
163 in Iloilo City, this research aspires to improve outbreak responses through cutting-
164 edge technology rather than traditional reporting methods.

165 1.2 Problem Statement

166 Dengue remains a critical public health challenge worldwide, with cases increasing
167 due to the easing of COVID-19 restrictions and heightened global mobility. While
168 a temporary decline in cases was observed during the pandemic (2020–2022) due
169 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
170 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
171 regions like the Philippines, the threat is particularly severe. In Iloilo City and
172 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
173 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
174 pital beds occupied by dengue patients, highlighting the urgent need for effective
175 predictive tools. The lack of a reliable system to monitor and forecast dengue
176 outbreaks contributes to delayed interventions, exacerbating public health risks
177 and healthcare burdens in the region.

178 1.3 Research Objectives

179 1.3.1 General Objective

180 This study aims to develop an AI-based dengue forecasting and monitoring system
181 for Iloilo City and Province. The researchers will train and compare multiple deep
182 learning models to predict dengue case trends based on climate data and historical
183 dengue cases to help public health officials in possible dengue case outbreaks.

184 1.3.2 Specific Objectives

185 Specifically, this study aims to:

- 186 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
187 (including temperature, rainfall, wind, and humidity) from online sources.
188 Combine and aggregate these data into a unified dataset to facilitate com-
189 prehensive dengue case forecasting.
- 190 2. Evaluate deep learning models for predicting dengue cases using metrics
191 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
192 and Mean Squared Error (MSE). Compare the performance of these models
193 to determine the most accurate forecasting approach.
- 194 3. Develop a web-based analytics dashboard that integrates a predictive model
195 and provides data management system for dengue cases in Iloilo City and
196 the Province.
- 197 4. Assess the usability and effectiveness of the analytics dashboard through
198 structured feedback and surveys involving health professionals and policy-
199 makers.

200 1.4 Scope and Limitations of the Research

201 This study aims to gather dengue data from the Iloilo Provincial Health Office
202 and climate data from online sources such as PAGASA or weatherandclimate.com.
203 These data will be preprocessed, cleaned, and combined into a unified dataset to
204 facilitate comprehensive dengue case forecasting. However, the study is limited by
205 the availability and completeness of historical data. Inconsistent or missing data
206 points may introduce biases and reduce the quality of predictions. Furthermore,
207 the granularity of the data will be in a weekly format.

208 To evaluate deep learning models for predicting dengue cases, the study will
209 train and compare the performance of various models, using metrics like Mean
210 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
211 aim to provide accurate forecasts, their performance is heavily influenced by the
212 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
213 predictions. Additionally, the models cannot fully account for external factors
214 such as public health interventions or socio-economic conditions which may impact
215 dengue transmission dynamics.

216 The study also involves developing a web-based analytics dashboard that in-
217 tegrates predictive models and provides a data management system for dengue
218 cases in Iloilo City and the Province. This dashboard will offer public health
219 officials an interactive interface to visualize dengue trends, input new data, and

220 identify risk areas. However, its usability depends on feedback from stakeholders,
221 which may vary based on their familiarity with analytics tools. Moreover, exter-
222 nal factors such as limited internet connectivity or device availability in remote
223 areas may affect the system’s adoption and effectiveness. While the dashboard
224 provides valuable insights, it cannot incorporate all factors influencing dengue
225 transmission, emphasizing the need for ongoing validation and refinement.

226 1.5 Significance of the Research

227 This study’s development of an AI-based dengue forecasting and monitoring sys-
228 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 229 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
230 and local health units in Iloilo City and Province stand to benefit greatly
231 from the system. With dengue predictions, we can help these agencies opti-
232 mize their response strategies and implement targeted prevention measures
233 in high-risk areas before cases escalate.
- 234 • **Local Government Units (LGUs):** LGUs can use the system to support
235 their disaster management and health initiatives by proactively addressing
236 dengue outbreaks. The predictive insights allow for more efficient planning
237 and resource deployment in barangays and communities most vulnerable to
238 outbreaks, improving overall public health outcomes.
- 239 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
240 occupancy rates during dengue season will benefit from early outbreak fore-
241 casts that can help in managing patient inflow and ensuring adequate hos-
242 pital capacity.
- 243 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
244 able insights for researchers studying infectious disease patterns and policy-
245 makers focused on strengthening the national AI Roadmap. The system’s
246 data can support broader initiatives for sustainable health infrastructure
247 and inform policy decisions on resource allocation for dengue control.
- 248 • **Community Members:** By reducing the frequency and severity of outbreaks,
249 this study ultimately benefits the community at large. This allows for timely

250 awareness campaigns and community engagement initiatives, empowering
251 residents with knowledge and preventative measures to protect themselves
252 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

276 public health concern. Studies suggest that outbreak thresholds should be context-
277 specific, given the variability in transmission dynamics across different locations
278 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
279 Channel often base thresholds on 2 standard deviations (SD) above the mean
280 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
281 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
282 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
283 significantly across regions and time, making them inconsistent and incomparable.

284 From the studies above, this research implements an outbreak definition basing
285 the threshold on 2 standard deviations (SD) above the mean number of historic
286 dengue cases. It is important to note that for future outbreak definitions, addi-
287 tional local context like available hospital space etc., must be taken into account
288 for a more effective outbreak definition.

289 **2.3 Existing System: RabDash DC**

290 RabDash, developed by the University of the Philippines Mindanao, is a web-
291 based dashboard for rabies data analytics. It combines predictive modeling with
292 genomic data, enabling local health authorities to optimize interventions and al-
293 locate resources more effectively. RabDash’s modules include trend visualization,
294 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
295 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

296 For DengueWatch, RabDash serves as a strong inspiration, particularly in
297 its monitoring, historical trend visualization, and forecasting capabilities. These
298 features align well with the needs of dengue control efforts, providing real-time
299 insights into outbreak trends and enabling more effective, data-driven decision-
300 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
301 breaks similarly require time-series forecasting models. By using LSTM, RabDash
302 effectively models trends in outbreak data, which provides a framework for adapt-
303 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
304 form traditional methods, such as ARIMA and MLP, in handling the complexities
305 of time-dependent epidemiological data (Ligue & Ligue, 2022).

306 2.4 Deep Learning

307 The study of (Ligue & Ligue, 2022) highlights how data-driven models can help
308 predict dengue outbreaks. The authors compared traditional statistical meth-
309 ods, such as non-seasonal and seasonal autoregressive integrated moving average
310 (ARIMA), and traditional feed-forward network approach using a multilayer per-
311 ceptron (MLP) model with a deep learning approach using the long short-term
312 memory (LSTM) architecture in their prediction model. They found that the
313 LSTM model performs better in terms of accuracy. The LSTM model achieved a
314 much lower root mean square error (RMSE) compared to both MLP and ARIMA
315 models, proving its ability to capture complex patterns in time-series data (Ligue
316 & Ligue, 2022). This superior performance is attributed to LSTM’s capacity
317 to capture complex, time-dependent relationships within the data, such as those
318 between temperature, rainfall, humidity, and mosquito populations, all of which
319 contribute to dengue incidence (Ligue & Ligue, 2022).

320 2.5 Kalman Filter

321 The Kalman Filter is another powerful tool for time-series forecasting that can be
322 integrated into our analysis. It provides a recursive solution to estimating the state
323 of a linear dynamic system from a series of noisy measurements. Its application
324 in epidemiological modeling can enhance prediction accuracy by accounting for
325 uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters
326 are effective in predicting infectious disease outbreaks by refining estimates based
327 on observed data. A study published in *Frontiers in Physics* utilized the Kalman
328 filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman
329 filter effectively tracked the progression of deaths and cases, providing critical in-
330 sights for public health decision-making (Ahmadini et al., 2021). Another research
331 article in *PLOS ONE* focused on tracking the effective reproduction number (R_t)
332 of COVID-19 using a Kalman filter. This method estimated the growth rate of
333 new infections from noisy data, demonstrating that the Kalman filter could main-
334 tain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli,
335 Bullano, Kucinskas, & Rondón-Moreno, 2021).

336 Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM
337 models using our own collected dengue case data along with weather data to
338 identify the most effective model for real-time forecasting.

2.6 Weather Data

The relationship between weather patterns and mosquito-borne diseases is inherently nonlinear, meaning that fluctuations in disease cases do not respond proportionally to changes in climate variables (Colón-González, Fezzi, Lake, & Hunter, 2013). Weather data, such as minimum temperature and accumulated rainfall, are strongly linked to dengue case fluctuations, with effects observed after several weeks due to mosquito breeding and virus incubation cycles. Integrating these lagged weather effects into predictive models can improve early warning systems for dengue control (Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests that weather-based forecasting models using variables like mean temperature and cumulative rainfall can provide early warnings of dengue outbreaks with high sensitivity and specificity, enabling predictions up to 16 weeks in advance (Hii, Zhu, Ng, Ng, & Rocklöv, 2012).

We will utilize weather data, including variables such as temperature, rainfall, and humidity, as inputs for our dengue forecasting model. Given the strong, nonlinear relationship between climate patterns and dengue incidence, these weather variables, along with their lagged effects, are essential for enhancing prediction accuracy and providing timely early warnings for dengue outbreaks.

2.7 Chapter Summary

This chapter reviewed key literature relevant to our study, focusing on existing systems, predictive modeling techniques and the role of weather data in forecasting dengue outbreaks. We examined systems like RabDash DC, which integrates predictive modeling with real-time data to inform public health decisions, providing a foundational structure for our Dengue Watch System. Additionally, deep learning approaches, particularly Long Short-Term Memory (LSTM) networks, were highlighted for their effectiveness in time-series forecasting, while alternative methods such as ARIMA and Kalman Filters were considered for their ability to model complex temporal patterns and handle noisy data.

The literature further underscores the significance of weather variables—such as temperature and rainfall—in forecasting dengue cases. Studies demonstrate that these variables contribute to accurate outbreak prediction models. Leveraging these insights, our study will incorporate both weather data and historical dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

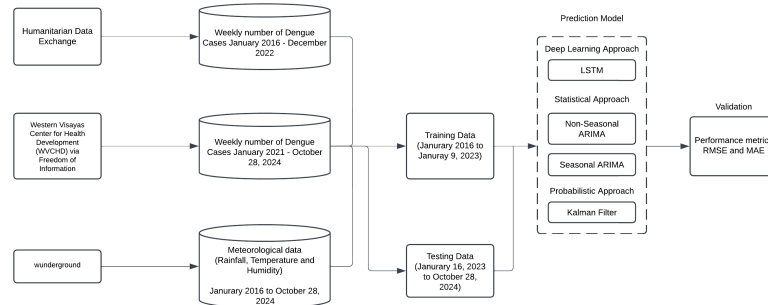

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

3.1 Research Activities

3.1.1 Gather Dengue Data and Climate Data to Create a Complete Dataset for Forecasting

Acquisition of Dengue Case Data

The historical dengue case dataset used in this study was obtained from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD) via Freedom of Information (FOI) requests. The decision to use weekly intervals was driven by the need for precision and timeliness in capturing fluctuations in dengue cases and weather conditions. Dengue transmission is influenced by short-term changes in weather variables such as rainfall and temperature, which impact mosquito breeding and virus transmission cycles. A weekly granularity allowed the model to better capture these short-term trends, enabling more accurate predictions and responsive public health interventions.

Moreover, using a weekly interval provided more data points for training the models compared to a monthly format. This is particularly critical in time series modeling, where larger datasets help improve the robustness of the model and its ability to generalize to new data. Also, the collection of weather data was done by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall, temperature, and humidity) from Weather Underground (wunderground.com).

Data Fields

- **Time.** Represents the specific year and week corresponding to each entry in the dataset.
- **Rainfall.** Denotes the observed average rainfall, measured in millimeters, for a specific week.
- **Humidity.** Refers to the observed average relative humidity, expressed as a percentage, for a specific week.
- **Max Temperature.** Represents the observed maximum temperature, measured in degrees Celsius, for a specific week.
- **Average Temperature.** Represents the observed average temperature, measured in degrees Celsius, for a specific week.

- 415 • **Min Temperature.** Represents the observed minimum temperature, mea-
416 sured in degrees Celsius, for a specific week.
- 417 • **Wind.** Represents the observed wind speed, measured in miles per hour
418 (mph), for a specific week.
- 419 • **Cases.** Refers to the number of reported dengue cases during a specific
420 week.

421 **Data Integration and Preprocessing**

422 The dengue case data was integrated with the weather data to create a com-
423 prehensive dataset, aligning the data based on corresponding timeframes. The
424 dataset underwent a cleaning process to address any missing values, outliers, and
425 inconsistencies to ensure its accuracy and reliability. To ensure that all features
426 and the target variable were on the same scale, a MinMaxScaler was applied to
427 normalize both the input features (climate data) and the target variable (dengue
428 cases).

429 **Exploratory Data Analysis (EDA)**

- 430 • Analyzed trends, seasonality, and correlations between dengue cases and
431 weather factors.
- 432 • Created visualizations like time series plots and scatterplots to highlight
433 relationships and patterns in the data.

434 **Outbreak Detection**

435 To detect outbreaks, we computed the outbreak threshold value of dengue cases
436 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

437 where μ is the historical mean and σ is the standard deviation.

438 3.1.2 Develop and Evaluate Deep Learning Models for 439 Dengue Case Forecasting

440 The deep learning models were developed and trained to forecast weekly dengue
441 cases using historical weather data (rainfall, temperature, wind, and humidity)
442 and dengue case counts. The dataset was normalized and divided into training and
443 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
444 for preparing and training the model are outlined below.

445 Data Preprocessing

446 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
447 ture, wind, humidity) and dengue case counts. The "Time" column was converted
448 to a datetime format to ensure proper temporal indexing. To standardize the data
449 for training, MinMaxScaler was employed, normalizing the feature values and tar-
450 get variable to a range of 0 to 1. This step ensured that the models could efficiently
451 process the data without being biased by feature scaling differences.

452 LSTM Model

453 To prepare the data for LSTM, a sliding window approach was utilized. Sequences
454 of weeks of normalized features were constructed as input, while the dengue case
455 count for the subsequent week was set as the target variable. This approach en-
456 sured that the model leveraged temporal dependencies in the data for forecasting.

457 The LSTM model was designed using the TensorFlow and Keras libraries. The
458 architecture comprised the following layers:

- 459 • Input Layer: Accepting sequences of weeks with three features (rainfall, max
460 temperature, and humidity).
- 461 • LSTM Layer: A single LSTM layer with 64 units and ReLU activation,
462 capturing temporal dependencies and feature interactions.
- 463 • Dense Output Layer: A fully connected layer with a single neuron to predict
464 the dengue cases for the next week.

465 The model was trained for 100 epochs implementing early stopping with a batch
466 size of 1, enabling fine-grained weight updates. The training dataset consisted

467 of 80% of the sequences, while the remaining 20% was used as the test set to
468 evaluate model performance. Validation loss was monitored during training to
469 assess model generalization.

470 The training process was conducted using three distinct window sizes (5 weeks,
471 10 weeks, and 20 weeks) to determine the optimal sequence length of weeks to
472 input into the LSTM model for improved forecasting performance.

473 After training, predictions on both the training and test datasets were rescaled
474 to their original scale using the inverse transformation of MinMaxScaler. Model
475 performance was evaluated using the mean squared error (MSE), root mean
476 squared error (RMSE) and mean absolute error (MAE).

477 **Hyperparameter Tuning**

478 After identifying the optimal window size, it is saved and used to generate the
479 final data sequences, which are then utilized during hyper-parameter tuning.

480 To enhance the performance of the LSTM model in predicting dengue cases,
481 Bayesian Optimization was employed using the Keras Tuner library. The tuning
482 process aimed to minimize the validation loss (mean squared error) by adjusting
483 key model hyper-parameters, specifically:

- 484 • **LSTM units:** Ranged from 32 to 256 with a step size of 32
- 485 • **Learning Rate:** Sampled logarithmically between 0.00001 and 0.001

486 The tuner was instantiated with:

- 487 • **max trials = 10:** Limiting the search to 10 different configurations
- 488 • **executions per trial = 2:** Running each configuration twice to reduce
489 variance
- 490 • **validation split = 0.2:** Reserving 20% of the training data for validation

491 **ARIMA**

492 The ARIMA model was employed to forecast weekly dengue cases using historical
493 weather data (rainfall, max temperature, and humidity) as exogenous variables

494 and historical case counts as the primary dependent variable. The dataset was
495 split into training (80

- 496 • p (autoregressive order): 0 to 3
- 497 • d (differencing order): 0 to 2
- 498 • q (moving average order): 0 to 3

499 The combinations of these parameters were evaluated by fitting an ARIMA model
500 for each set of (p, d, q) values. The model's performance was assessed using the
501 mean squared error (MSE) between the predicted and actual dengue cases in the
502 test set. The combination yielding the lowest MSE was selected as the optimal
503 parameter configuration.

504 The fitted ARIMA model was used to forecast weekly dengue cases for the
505 test dataset. Predictions were directly assigned to the PredictedCases column in
506 the test dataset.

507 Steps to Create the ARIMA Model:

- 508 1. **Data Preprocessing:** Prepare the dataset by handling any missing values
509 and scaling the data if necessary to improve model convergence and stability.
- 510 2. **Hyperparameter Tuning:** Use a grid search on potential ARIMA param-
511 eters (p, d, q) to identify the configuration that minimizes error. The optimal
512 parameters were found to be **(1, 2, 2)**.
- 513 3. **Model Training:**
 - 514 • Set the number of iterations to 400 to ensure thorough training and
515 convergence.
 - 516 • Train the ARIMA model on 80% of the data and reserve 20% for test-
517 ing.

518 Seasonal ARIMA (SARIMA)

519 1. Data Preprocessing

- 520 • Handle missing values through interpolation or imputation.
- 521 • Normalize or standardize features to ensure stable training.

- Split data into training (80%) and testing (20%) sets while maintaining temporal continuity.

2. Seasonality Analysis

- Perform time series decomposition to examine trend, seasonality, and residual components.
- Identify seasonality using autocorrelation plots and spectral analysis.
- A periodicity of **52 weeks** was detected, justifying the use of a seasonal model.

3. Hyperparameter Tuning

- Conduct a grid search to optimize SARIMA parameters $(p, d, q)(P, D, Q)[S]$.
- Determine optimal configuration for seasonal and non-seasonal components.
- Verify stationarity through Augmented Dickey-Fuller (ADF) test.

4. Model Training

- Fit the SARIMA model on the training dataset, incorporating exogenous variables such as rainfall, temperature, and humidity.
- Set a maximum number of iterations to ensure convergence.
- Monitor model diagnostics (residual analysis) to confirm the absence of autocorrelation in residuals.

5. Forecasting and Validation

- Generate out-of-sample forecasts for future dengue cases.
- Compare predicted values against actual data to assess real-world applicability.
- Visualize results with line plots and confidence intervals.

Kalman Filter:

- Input Variables: The target variable (Cases) was modeled using three regressors: rainfall, max temperature, and humidity.
- Training and Testing Split: The dataset was split into 80% training and 20% testing to evaluate model performance.

551 • **Observation Matrix:** The Kalman Filter requires an observation matrix,
552 which was constructed by adding an intercept (column of ones) to the re-
553 gressors.

554 The Kalman Filter’s EM method was employed for training, iteratively esti-
555 mating model parameters over 10 iterations. The smooth method was used to
556 compute the smoothed state estimates for the training data. Observation matri-
557 ces for the test data were constructed similarly, ensuring compatibility with the
558 trained model.

559 3.2 Kalman Filter

560 • **Input Variables:** The target variable (Cases) was modeled using three
561 regressors: rainfall, max temperature, and humidity.

562 • **Training and Testing Split:** The dataset was split into 80% training and
563 20% testing to evaluate model performance.

564 • **Observation Matrix:** The Kalman Filter requires an observation matrix,
565 which was constructed by adding an intercept (column of ones) to the re-
566 gressors.

567 The Kalman Filter’s EM method was employed for training, iteratively esti-
568 mating model parameters over 10 iterations. The smooth method was used to
569 compute the smoothed state estimates for the training data. Observation matri-
570 ces for the test data were constructed similarly, ensuring compatibility with the
571 trained model.

572 3.3 Kalman Filter Methodology with Matrix Cal- 573 culations

574 **Measurement Acquisition:** Obtain the measurement: (z_k) of the system’s state
575 with associated confidence. This measurement matrix provides a noisy observation
576 of the true state.

577 The dataset was split into training and test sets to evaluate the Kalman Filter’s
578 performance and generalizability:

579 • **Training Set:** 80% of the data was used for training, enabling the Kalman
580 Filter model to capture key patterns.

581 • **Test Set:** The remaining 20% of the data was reserved for testing.

582 **Prediction Step:**

583 • Predict the next state:

$$\hat{x}_{k|k-1} = A\hat{x}_{k-1|k-1} + Bu_k$$

584 • Update the state covariance:

$$P_{k|k-1} = AP_{k-1|k-1}A^T + Q$$

585 where Q is the process noise covariance matrix.

586 **Compute Residual:** Calculate the residual:

$$y_k = z_k - H\hat{x}_{k|k-1}$$

587 where H is the observation matrix. This residual represents the new information
588 from the measurement.

589 **Scaling Factor (Kalman Gain):**

590 • Compute the Kalman Gain:

$$K_k = P_{k|k-1}H^T (HP_{k|k-1}H^T + R)^{-1}$$

591 where R is the measurement noise covariance matrix.

592 • The Kalman Gain determines the weight of the measurement relative to the
593 prediction.

594 **State Update:**

595 • Update the state estimate:

$$\hat{x}_{k|k} = \hat{x}_{k|k-1} + K_k y_k$$

596 blending the prediction and measurement.

597 **Uncertainty Update:**

598 • Update the state covariance:

$$P_{k|k} = (I - K_k H)P_{k|k-1}$$

599 where I is the identity matrix.

600 **3.3.1 Integrate the Predictive Model into a Web-Based** 601 **Data Analytics Dashboard**

602 **Dashboard Design and Development**

- 603 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 604 – Interactive visualizations of yearly dengue case trends.
 - 605 – Data input and update forms for dengue and weather data.
 - 606 – Map display of dengue cases in each district in Iloilo City

607 **Model Integration and Deployment**

- 608 • Deploy the best-performing model within the dashboard as a backend service
609 to enable real-time or periodic forecasting.

610 **3.3.2 System Development Framework**

611 The Agile Model is the birthchild of both iterative and incremental approaches
612 in Software Engineering. It aims to be flexible and effective at the same time by
613 being adaptable to change. It's also important to note that small teams looking
614 to construct and develop projects quickly can benefit from this kind of method-
615 ology. As the Agile Method focuses on continuous testing, quality assurance is a
616 guarantee since bugs and errors are quickly identified and patched.

617 **3.3.3 Design, Building, Testing, and Integration**

618 **Design and Development**

619 After brainstorming and researching the most appropriate type of application to
620 accommodate both the prospected users and the proposed solutions, the team has
621 decided to proceed with a web application. Given the time constraints and avail-
622 able resources, we believe this is the most pragmatic and practical move. The next
623 step is to select modern and stable frameworks that align with the fundamental
624 ideas we have learned at the university. The template obtained from WVCHD
625 and Iloilo Provincial Epidemiology and Surveillance Unit was meticulously ana-
626 lyzed to create use cases and develop a preliminary well-structured database that

627 adheres to the requirements needed to produce a quality application. The said use
628 cases serve as the basis of general features. Part by part, these are converted into
629 code, and with the help of selected libraries and packages, it resulted in the de-
630 sired outcome that may still modified and extended since it is continuously being
631 developed.

632 **Testing and Integration**

633 Each feature will be rigorously user-tested to ensure quality assurance, with par-
634 ticular emphasis on prerequisite features, as development cannot progress properly
635 if these fail. Moreover, integration between each feature serves as a pillar for a
636 cohesive user experience. Presently, we have not been able to use performance
637 metrics to measure the system’s performance, as developing and connecting the
638 core features is the utmost priority.

639 **3.4 Development Tools**

640 **3.4.1 Software**

641 **Github**

642 GitHub is a cloud-based platform that tracks file changes using Git, an open-
643 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
644 used in the project to store the application’s source code, manage the system’s
645 source version control, and serve as a repository for the Latex files used in the
646 actual research.

647 **Visual Studio Code**

648 Visual Studio Code is a free, lightweight, and cross-platform source code editor
649 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
650 this project’s programming and scripting languages, it was chosen as the primary
651 source code editor.

652 Django

653 Django is a free and open-sourced Python-based web framework that offers an
654 abstraction to develop and maintain a secure web application. As this research
655 aims to create a well-developed and maintainable application, it is in the best
656 interest to follow an architectural pattern that developers and contributors in the
657 future can understand. Since Django adheres to Model-View-Template (MVT)
658 that promotes a clean codebase by separating data models, business logic, and
659 presentation layers, it became the primary candidate for the application's back-
660 bone.

661 Next.js

662 A report by Statista (2024) claims that React is the most popular front-end frame-
663 work among web developers. However, React has limitations that can be a nui-
664 sance in rapid software development, which includes routing and performance op-
665 timizations. This is where Next.js comes in—a framework built on top of React.
666 It offers solutions for React's deficiency, making it a rising star in the framework
667 race.

668 Postman

669 As the application heavily relies on the Application Programming Interface (API)
670 being thrown by the backend, it is a must to use a development tool that facilitates
671 the development and testing of the API. Postman is a freemium API platform
672 that offers a user-friendly interface to create and manage API requests (*What is*
673 *Postman? Postman API Platform*, n.d.).

674 3.4.2 Hardware

675 The web application is continuously being developed on laptop computers with
676 minimum specifications of an 11th-generation Intel i5 CPU and 16 gigabytes of
677 RAM.

678 3.4.3 Packages

679 Django REST Framework

680 Django Rest Framework (DRF) is a third-party package for Django that provides a
681 comprehensive suite of features to simplify the development of robust and scalable
682 Web APIs (Christie, n.d.). These services include Serialization, Authentication
683 and Permissions, Viewsets and Routers, and a browsable API .

684 Leaflet

685 One of the features of the web application is the ability to map the number
686 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
687 most importantly, stable JavaScript package that can do the job. With its ultra-
688 lightweight size, it offers a comprehensive set of features that does not trade
689 off performance and usability (*Leaflet — an open-source JavaScript library for*
690 *interactive maps*, n.d.).

691 Chart.js

692 Another feature of the application is to provide users with informative, approach-
693 able data storytelling that is easy for everyone to understand. The transformation
694 of pure data points and statistics into figures such as charts is a big factor. Thus,
695 there is a need for a package that can handle this feature without compromising
696 the performance of the application. Chart.js is a free and open-source JavaScript
697 package that is made to meet this criteria as it supports various types of charts
698 (*Chart.js*, n.d.).

699 Tailwind CSS

700 Using plain CSS in production-quality applications can be counterproductive.
701 Therefore, CSS frameworks were developed to promote consistency and accelerate
702 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
703 which offers low-level utility classes that can be applied directly to each HTML
704 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
705 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
706 project, using this framework is a wise choice due to its stability and popularity
707 among developers.

708 **Shadcn**

709 Shadcn offers a collection of open-source UI boilerplate components that can be
710 directly copied and pasted into one's project. With the flexibility of the provided
711 components, Shadcn allows developers to have full control over customization and
712 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
713 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

714 **Zod**

715 Data validation is integral in this web application since it will handle crucial data
716 that will be used for analytical inferences and observations. Since Zod is primarily
717 used for validating and parsing data, it ensures proper communication between
718 the client and the server (Zod, n.d.).

719 3.5 Calendar of Activities

720 A Gantt chart showing the schedule of the activities is included below. Each
 721 bullet represents approximately one week of activity.

Table 3.1: Timetable of Activities for 2024

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. **Dengue Case Data:** The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. **Weather Data:** Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

```
data.head()

740 4.2 Exploratory Data Analysis

741 From the summary above, the dataset consists of 720 weekly records with 8
742 columns:

- 743 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 744 • **Rainfall.** Weekly average rainfall (mm)
- 745 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
746 temperature data (C)
- 747 • **Wind.** Wind speed (m/s)
- 748 • **Humidity.** Weekly average humidity (%)
- 749 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases

std	NaN	35.448846	2.616379	0.999800	1.291659	2.446703	2.831674	37.144813

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks.

To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

762 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 763 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

764

765 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 766 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 767 dengue cases. Notably, peak cases are observed during certain periods approx-
 768 imately 3 years, potentially aligning with specific climatic conditions such as
 769 increased rainfall or temperature changes. This underscores the importance of
 770 incorporating climate variables into the forecasting model.

771 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 772 and selected features, including rainfall, humidity, maximum temperature, aver-
 773 age temperature, minimum temperature, and wind speed. Among these, rainfall
 774 exhibits the highest positive correlation with dengue cases (correlation coefficient
 775 0.13), indicating that increased rainfall may contribute to higher cases counts.
 776 This aligns with existing studies suggesting that stagnant water from heavy rain-
 777 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 778 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 779 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 780 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 781 relationship than average and minimum temperature.

782 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 783 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

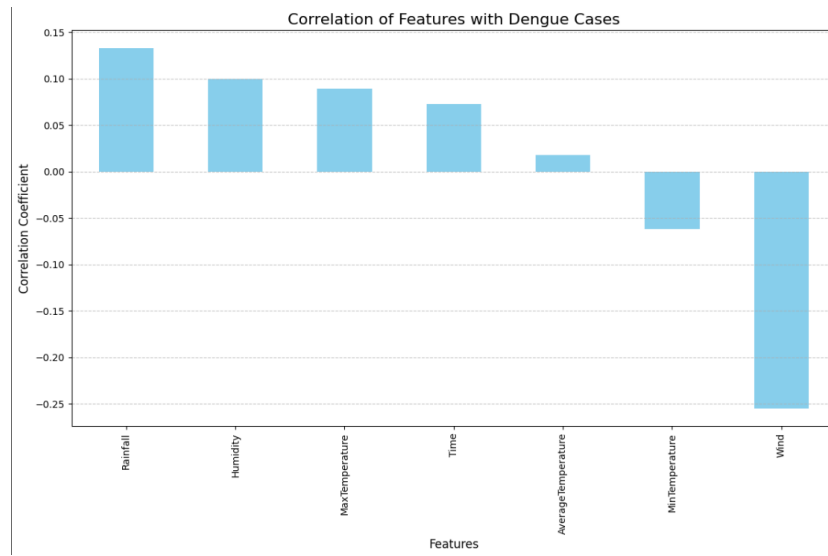

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

4.3 Outbreak Detection

To identify outbreaks, we calculated the outbreak threshold value using the historical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

where μ is the historical mean and σ is the standard deviation.

This result indicates that dengue cases exceeding 98 in Iloilo City can be considered an outbreak. However, it is important to note that this threshold serves only as a baseline. Additional parameters, such as the number of hospital beds available in the city, must be considered to compute a more effective threshold and develop an appropriate response strategy.

798 4.4 Model Training

799 The proposed Dengue Watch system utilized four distinct models to forecast
800 weekly dengue cases: Long Short-Term Memory (LSTM) networks, Autoregres-
801 sive Integrated Moving Average (ARIMA), Seasonal ARIMA (SARIMA), and
802 Kalman Filter. Each model was trained on a dataset containing 720 weeks of
803 historical dengue cases from 2011 to 2024, with meteorological variables such as
804 max temperature, humidity, and rainfall.

805 Using SARIMA and LSTM for dengue forecasting requires an adaptive ap-
806 proach due to seasonal changes and long-term trends. Dengue case data is updated
807 every month, and weather data can be extracted manually every week. By contin-
808 uously monitoring performance, incorporating external factors, and updating the
809 model regularly (preferably monthly or semi-annually), forecasting accuracy can
810 be maintained. If drastic environmental or epidemiological changes occur, more
811 frequent retraining is necessary. This ensures that public health interventions
812 remain proactive, effectively mitigating dengue outbreaks.

813 To optimize predictive performance, hyperparameter tuning was conducted
814 individually for each model, refining parameters to achieve the most accurate and
815 reliable forecasts. Following training, the models were rigorously evaluated against
816 the dataset using a set of key performance metrics, including Mean Squared Error
817 (MSE), Root Mean Squared Error (RMSE), and Mean Absolute Error (MAE).

818 The table below provides a summary and comparative analysis of each model's
819 results across these metrics, offering insights into the strengths and limitations of
820 each forecasting technique for dengue case prediction in Iloilo City. The acceptable
821 threshold for Mean Absolute Error (MAE) in forecasting dengue cases for it to be
822 considered accurate can vary depending on the context. However, related studies
823 often serve as benchmarks, with commonly cited acceptable values ranging from
824 20 to 30. For this study, we have established a threshold of 15 to emphasize the
825 significance of accurate dengue prediction.

Model	MSE	RMSE	MAE
LSTM	260.93	16.15	9.30
Seasonal ARIMA (2, 0, 2) (0, 1,1)	1109.69	33.31	18.09
ARIMA (1, 2, 2)	1521.48	39.01	25.80
Kalman Filter	1474.82	38.40	22.34

Table 4.1: Comparison of Models

826 4.4.1 LSTM Model

827 The LSTM model architecture consisted of an input layer, a single LSTM layer
828 with 64 units and ReLU activation, followed by a dense layer with a single output
829 neuron to predict the dengue case count. Key hyperparameters included:

- 830 • Window Size: 5, 10, and 20 weeks, representing the time steps used in the
831 sequence data for each prediction.
- 832 • Epochs: 100 epochs were used for training, balancing sufficient training
833 time with computational efficiency also implementing early stopping to avoid
834 overfitting.
- 835 • Batch Size: 1, allowing the model to process one sequence at a time, which
836 is beneficial for small datasets but increases training time.
- 837 • Optimizer: The Adam optimizer was chosen for its adaptive learning capa-
838 bilities and stability in training. A custom learning rate of 0.001 was set to
839 ensure gradual convergence and minimize risk of overfitting.

840 The dataset was split into training and test sets to evaluate the model's per-
841 formance and generalizability:

- 842 • **Training Set:** 80% of the data (572 sequences) was used for model training,
843 enabling the LSTM to learn underlying patterns in historical dengue case
844 trends and their relationship with weather variables.
- 845 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
846 testing

847 The training process was conducted using three distinct window sizes—5 weeks,
848 10 weeks, and 20 weeks—to identify the optimal sequence length of weeks for input
849 into the LSTM model, thereby enhancing forecasting performance. The following
850 plots illustrate the performance of the model in predicting dengue cases for each
851 of the specified window sizes.

Figure 4.9: Comparison of Window Sizes

852 The evaluation metrics included Mean Squared Error (MSE), Root Mean
 853 Squared Error (RMSE), Mean Absolute Error (MAE) and R^2 Score, which as-
 854 sess the accuracy of the model's predictions.

Window Size	MSE	RMSE	MAE	R^2
5	274.70	16.57	9.57	0.84
10	260.93	16.15	9.30	0.85
20	297.11	17.24	9.84	0.83

Table 4.2: Comparison of Window Sizes

854

855 The results indicate that a window size of 10 weeks provides the most accurate
 856 predictions, as evidenced by the lowest MSE (260.93) and RMSE (16.15) values.
 857 Although the 10-week window size yields the lowest MAE (9.30), the 5-week
 858 window follows closely with 9.57, while the 20-week window is slightly higher at
 859 9.84. These differences are relatively small, especially between the 5- and 10-week
 860 windows, indicating that the average prediction error remains fairly consistent
 861 across different window sizes.

862 Furthermore, the R^2 score of 0.85 for the 10-week window indicates that 85%

of the variability in the target variable (cases) is explained by the independent variables (the inputs) in the model, making it a reliable configuration overall. In contrast, the 5-week and 20-week windows yield R^2 scores of 0.84 and 0.83, respectively, reflecting marginally lower explanatory power.

This suggests that using a 10-week sequence length effectively balances the model’s ability to capture temporal dependencies with predictive accuracy, without unnecessarily increasing model complexity or introducing additional noise from longer sequences.

Hyperparameter Tuning

Using the 10-week sequence length identified as the optimal window size in preliminary experiments, the dataset was reshaped accordingly and served as the input for hyperparameter tuning. The tuning process was conducted using the *Bayesian Optimization* approach provided by the **Keras Tuner** library, targeting the minimization of validation loss (Mean Squared Error). The key hyperparameters explored during the tuning were:

- **LSTM units:** 256
- **Learning Rate:** 0.001

Although the tuning process successfully identified a configuration that minimized the validation loss during training, it did not result in improved performance on the test set. In fact, the model’s evaluation metrics slightly declined when compared to the baseline model trained with manually selected hyperparameters.

Model	MSE	RMSE	MAE	R^2
Before tuning	260.93	16.15	9.30	0.85
After tuning	317.70	17.82	10.42	0.81

Table 4.3: Comparison of Model Performance Before and After Tuning (Using window size = 10)

This outcome suggests that the tuned model may have overfitted the validation split, a common occurrence when working with relatively small datasets. It is also possible that the default or manually chosen configuration was already close to optimal in terms of generalization. Furthermore, although the tuning search space was reasonably defined, it may have excluded other more effective hyperparameter combinations.

890 These results emphasize the importance of critically evaluating tuning results
891 and underscore that automated hyperparameter optimization does not always
892 guarantee better model performance on unseen data.

893 Training and Testing Data Division for ARIMA 894 and Seasonal Arima

895 Both models utilized an **80%-20% split** to evaluate generalizability:

- 896 • **Training Set:** 80% of the data was used for training, allowing the models
897 to learn underlying patterns in the dataset.
- 898 • **Test Set:** 20% of the data was reserved for testing, providing an unbiased
899 assessment of the models' performance on unseen data.

900 4.4.2 ARIMA Model

Figure 4.10: ARIMA Prediction Results for Test Set

901 The ARIMA model was developed to capture non-seasonal trends in the data. To
902 determine the best model configuration, grid search was used to explore various
903 combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**. The
904 model was iteratively refined over **400 iterations** to ensure convergence to an
905 optimal solution.

906 The model's performance was assessed using regression metrics to evaluate its
907 forecasting capability:

- 908 • Mean Squared Error (MSE): Quantifies average squared prediction error.
- 909 • Root Mean Squared Error (RMSE): Measures average prediction error on
910 the data's original scale.
- 911 • Mean Absolute Error (MAE): Measures the average magnitude of the abso-
912 lute errors between the predicted and actual values.

913 The ARIMA model yielded the following error metrics:

- 914 • **MSE (Mean Squared Error): 1521.48**
- 915 • **RMSE (Root Mean Squared Error): 39.01**
- 916 • **MAE (Mean Absolute Error): 25.80**

917 4.4.3 Seasonal ARIMA (SARIMA) Model

Figure 4.11: Seasonal ARIMA Prediction Results for Test Set

918 This model incorporates seasonal parameters, which were tuned using grid search
 919 to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA,
 920 **400 iterations** were applied to ensure a robust fit.

921 The model's performance was assessed using regression metrics to evaluate its
 922 forecasting capability:

- 923 • Mean Squared Error (MSE): Quantifies average squared prediction error.
- 924 • Root Mean Squared Error (RMSE): Measures average prediction error on
 925 the data's original scale.
- 926 • Mean Absolute Error (MAE): Measures the average magnitude of the abso-
 927 lute errors between the predicted and actual values.

928 The SARIMA model yielded the following error metrics:

- 929 • **MSE: 1109.69**

930 • **RMSE:** 33.31

931 • **MAE:** 18.09

932 The SARIMA model outperformed the ARIMA model in terms of lower MSE and
933 RMSE values, indicating its effectiveness in capturing the seasonal patterns in the
934 data.

935 4.4.4 Kalman Filter Model

Figure 4.12: Kalman Filter Prediction Results for Test Set

936 **Model Evaluation:** Upon testing, the Kalman Filter produced the following
937 error metrics:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

938 These results indicate the model's performance in predicting dengue cases,
939 where lower errors suggest a better fit to the observed data.

940 4.5 Preliminary System Requirements

941 4.5.1 Backend Requirements

942 Database Structure Design

943 Determining how data flows and how it would be structured is crucial in creating
 944 the system as it defines how extendible and flexible it would be for future features
 945 and updates. Thus, creating a comprehensive map of data ensures proper normal-
 946 ization that eliminates data redundancy and improves data integrity. Figure 4.13
 947 depicts the designed database schema that showcases the relationship between the
 948 application's entities.

Figure 4.13: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

949 4.5.2 User Interface Requirements

950 Admin Interface

Figure 4.14: Use Case Diagram for Admin

951 Figure 4.14 shows the possible tasks that the admin can do in the application. To
952 protect the integrity of data, only the admins can register and delete accounts.
953 Both account creation and deletion will be done within the application.

Figure 4.15: Use Case Diagram for Encoder

955 Figure 4.15, on the other hand, illustrates the use cases for the system's primary
956 users. Since only the admin accounts can register a user, the registration process
957 is not part of it. Instead, the main features, which include reporting and viewing
958 records, are the only permitted actions for this type of user. The said processes
959 can be done in the application by filling out a form with details required for each
960 dengue case. As data is entered, it will be consolidated for model training and
961 used for further forecasting of dengue cases.

962 4.5.3 Security and Validation Requirements

963 Password Encryption

964 Storing passwords as plain text in the database is a disgrace and a mortal sin in
965 production. It is important to implement precautionary methods such as hashing
966 and salting, followed by encryption with a strong algorithm, to prevent bad actors
967 from using the accounts for malicious transactions. By default, Django generates
968 a unique random salt for each password and encrypts it with Password-Based Key
969 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
970 techniques ensures that in the event of a data breach, cracking these passwords
971 would be time-consuming and useless for the attackers.

972 Authentication

973 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
974 the mechanism operates in a stateless manner, tokens are served only after a
975 successful login, eliminating the need for the server to keep a record of the token,
976 which is vulnerable to session hijacking. In addition, these tokens are signed with
977 a secret key, ensuring they have not been tampered with.

978 Data Validation

979 Both the backend and frontend should validate the input from the user to preserve
980 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
981 from the user. By doing this, the user can only send proper requests to the server
982 which streamlines the total workflow. On the other hand, Django has also a built-
983 in validator that checks the data type and ensures that the input matches the
984 expected format on the server side. These validation processes ensure that only
985 valid and properly formatted data is accepted, which reduces the risk of errors
986 and ensures consistency across the web application.

987 4.5.4 Testing Process

Figure 4.16: Testing Process for DengueWatch

988 As the system requirements and functionalities have been mentioned above, it
989 is important to implement testing to validate the system's performance and effi-
990 cacy. Since dengue reports include confidential information, anonymized historical
991 dengue reports were used to train the model and create the foundational architec-
992 ture of the system. By using functional tests, data validation and visualization can
993 be ensured for further continual improvements. Security testing is also important
994 as it is needed to safeguard confidential information when the system is deployed.
995 It includes proper authentication, permission views, and mitigating common in-
996 jection attacks. Finally, a user acceptance test from the prospected users, in this
997 case, the Iloilo City Epidemiology and Surveillance Unit, is crucial to assess its
998 performance and user experience. It enables the developers to confirm if the sys-
999 tem meets the needs of the problem, and once confirmed, it will be deployed and
1000 further evaluated to ensure stability and reliability in live operation.

1001 **4.6 System Prototype**

1002 **4.6.1 Guest Interface**

1003 The Guest Interface is intended for all visitors of the web application. It shows
1004 the related statistics for dengue cases in a particular area and time. As the system
1005 is still in its testing phase, the data converted into charts shown in Figure 4.17
1006 are generated from Python’s Faker library.

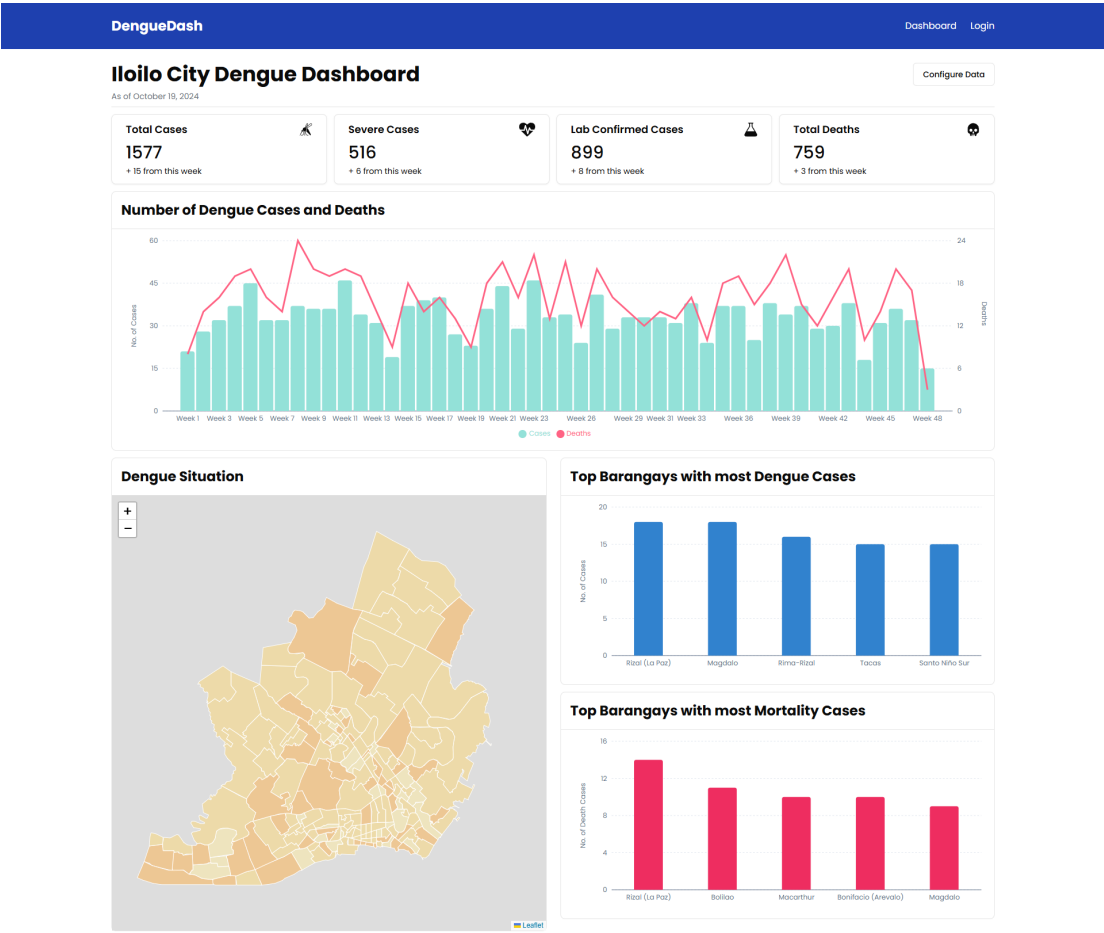

Figure 4.17: Dashboard for Guests

1007 **4.6.2 Personnel Interface**

1008 **User Authentication, and Login**

1009 To protect the data’s integrity in production, it has been decided that the regis-
1010 tration process will not be visible. Instead, an admin must register a user using
1011 a different interface. As of the moment, registering a user is done using API via
1012 Postman. In the login process, the system implements HTTP-only cookies that
1013 contains the JSON Web Tokens (JWT) to protect against XSS attacks. After
1014 proper credentials have been provided, it will redirect to the user’s home page.

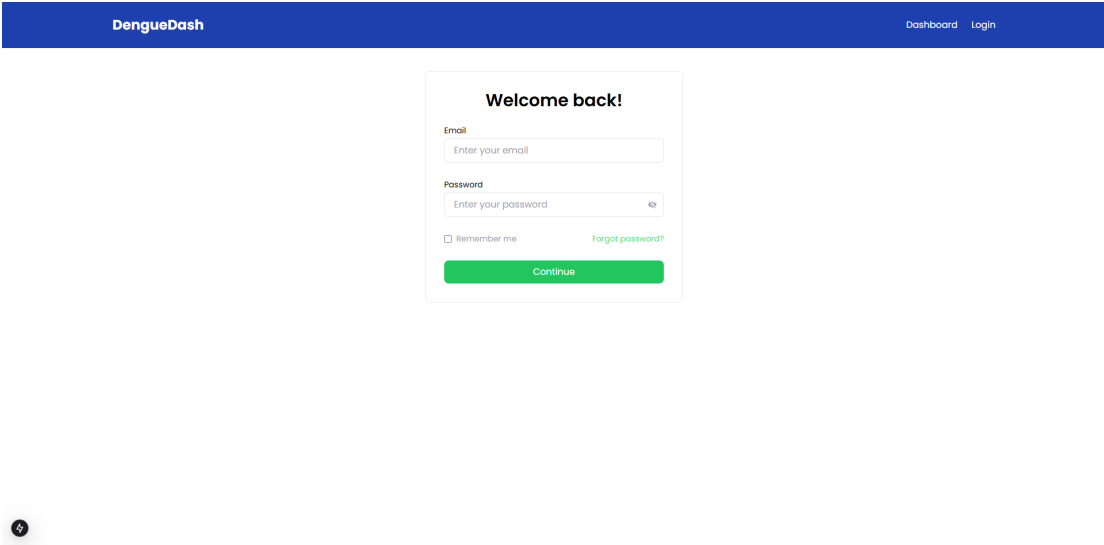

Figure 4.18: Login Page for Users

1015 **Encoder’s View**

1016 Figures 4.19 and 4.20 show the digitized counterpart of the form obtained from the
1017 Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to sup-
1018 port expandability for future features, some fields were modified to accommodate
1019 more detailed input. It is worth noting that all of the included fields adhere to the
1020 latest Philippine Integrated Disease and Surveillance Response (PIDSR) Dengue
1021 Forms, which the referenced form was based on. By doing this, it is assumed
1022 that the targeted users will have a familiarity when deployed on a national scale.
1023 On a further note, the case form includes the patient’s basic information, dengue
1024 vaccination status, consultation details, laboratory results, and the outcome.

Figure 4.20: Second Part of Case Report Form

1025 Once the data generated from the case report form is validated, it will be
1026 assigned as a new case and can be accessed through the Dengue Reports page, as
1027 shown in Figure 4.21. The said page displays basic information about the patient
1028 related to a specific case, including their name, address, date of consultation, and
1029 clinical and case classifications. It is also worth noting that it only shows cases
1030 the user is permitted to view. For example, in a local Disease Reporting Unit
1031 (DRU) setting, the user can only access records that came from the same DRU.
1032 On the other hand, in a consolidated surveillance unit such as a regional and
1033 provincial quarter, its users can view all the records that came from all the DRUs
1034 that report to them. Moving forward, Figure 4.22 shows the detailed case report
1035 of the patient on a particular consultation date.
