Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This research focused on developing a centralized system for monitoring and forecasting dengue trends in Iloilo City, incorporating graphical visualizations such as heatmaps, trends, and historical graphs. The study explored the application of artificial intelligence (AI) in dengue prediction, utilizing deep learning models. The performance of the Long Short-Term Memory (LSTM) model was compared with traditional statistical methods, including non-seasonal and seasonal Autoregressive Integrated Moving Average (ARIMA) models and the Kalman Filter. Evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) were used to identify the most effective model for integration into the system. Forecasting was based on climate variables such as temperature, rainfall, relative humidity, and previous monthly case counts. The LSTM model emerged as the best performer with an RMSE of 16.15, demonstrating its suitability for time-series predictions, while the Kalman Filter showed the poorest performance with an RMSE of 38.40. By integrating predictive analytics with real-time data visualization, the proposed system aims to support public health agencies, such as the Department of Health (DOH), by providing actionable insights for proactive intervention strategies. This AI-driven solution enhances traditional outbreak reporting systems by enabling timely, data-informed decisions to mitigate the impact of dengue in the region.

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

158 This study explores the monitoring and forecasting of dengue outbreaks by an-
159 alyzing key factors such as temperature, relative humidity, and historical dengue
160 cases, using different models. The findings aim to provide an advanced, AI-driven
161 alternative for dengue prevention and control, targeting agencies like the Depart-
162 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
163 in Iloilo City, this research aspires to improve outbreak responses through cutting-
164 edge technology rather than traditional reporting methods.

165 1.2 Problem Statement

166 Dengue remains a critical public health challenge worldwide, with cases increasing
167 due to the easing of COVID-19 restrictions and heightened global mobility. While
168 a temporary decline in cases was observed during the pandemic (2020–2022) due
169 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
170 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
171 regions like the Philippines, the threat is particularly severe. In Iloilo City and
172 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
173 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
174 pital beds occupied by dengue patients, highlighting the urgent need for effective
175 predictive tools. The lack of a reliable system to monitor and forecast dengue
176 outbreaks contributes to delayed interventions, exacerbating public health risks
177 and healthcare burdens in the region.

178 1.3 Research Objectives

179 1.3.1 General Objective

180 This study aims to develop an AI-based dengue forecasting and monitoring system
181 for Iloilo City and Province. The researchers will train and compare multiple deep
182 learning models to predict dengue case trends based on climate data and historical
183 dengue cases to help public health officials in possible dengue case outbreaks.

184 1.3.2 Specific Objectives

185 Specifically, this study aims to:

- 186 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
187 (including temperature, rainfall, wind, and humidity) from online sources.
188 Combine and aggregate these data into a unified dataset to facilitate com-
189 prehensive dengue case forecasting.
- 190 2. Evaluate deep learning models for predicting dengue cases using metrics
191 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
192 and Mean Squared Error (MSE). Compare the performance of these models
193 to determine the most accurate forecasting approach.
- 194 3. Develop a web-based analytics dashboard that integrates a predictive model
195 and provides data management system for dengue cases in Iloilo City and
196 the Province.
- 197 4. Assess the usability and effectiveness of the analytics dashboard through
198 structured feedback and surveys involving health professionals and policy-
199 makers.

200 1.4 Scope and Limitations of the Research

201 This study aims to gather dengue data from the Iloilo Provincial Health Office
202 and climate data from online sources such as PAGASA or weatherandclimate.com.
203 These data will be preprocessed, cleaned, and combined into a unified dataset to
204 facilitate comprehensive dengue case forecasting. However, the study is limited by
205 the availability and completeness of historical data. Inconsistent or missing data
206 points may introduce biases and reduce the quality of predictions. Furthermore,
207 the granularity of the data will be in a weekly format.

208 To evaluate deep learning models for predicting dengue cases, the study will
209 train and compare the performance of various models, using metrics like Mean
210 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
211 aim to provide accurate forecasts, their performance is heavily influenced by the
212 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
213 predictions. Additionally, the models cannot fully account for external factors
214 such as public health interventions or socio-economic conditions which may impact
215 dengue transmission dynamics.

216 The study also involves developing a web-based analytics dashboard that in-
217 tegrates predictive models and provides a data management system for dengue
218 cases in Iloilo City and the Province. This dashboard will offer public health
219 officials an interactive interface to visualize dengue trends, input new data, and

220 identify risk areas. However, its usability depends on feedback from stakeholders,
221 which may vary based on their familiarity with analytics tools. Moreover, exter-
222 nal factors such as limited internet connectivity or device availability in remote
223 areas may affect the system’s adoption and effectiveness. While the dashboard
224 provides valuable insights, it cannot incorporate all factors influencing dengue
225 transmission, emphasizing the need for ongoing validation and refinement.

226 1.5 Significance of the Research

227 This study’s development of an AI-based dengue forecasting and monitoring sys-
228 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 229 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
230 and local health units in Iloilo City and Province stand to benefit greatly
231 from the system. With dengue predictions, we can help these agencies opti-
232 mize their response strategies and implement targeted prevention measures
233 in high-risk areas before cases escalate.
- 234 • **Local Government Units (LGUs):** LGUs can use the system to support
235 their disaster management and health initiatives by proactively addressing
236 dengue outbreaks. The predictive insights allow for more efficient planning
237 and resource deployment in barangays and communities most vulnerable to
238 outbreaks, improving overall public health outcomes.
- 239 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
240 occupancy rates during dengue season will benefit from early outbreak fore-
241 casts that can help in managing patient inflow and ensuring adequate hos-
242 pital capacity.
- 243 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
244 able insights for researchers studying infectious disease patterns and policy-
245 makers focused on strengthening the national AI Roadmap. The system’s
246 data can support broader initiatives for sustainable health infrastructure
247 and inform policy decisions on resource allocation for dengue control.
- 248 • **Community Members:** By reducing the frequency and severity of outbreaks,
249 this study ultimately benefits the community at large. This allows for timely

250 awareness campaigns and community engagement initiatives, empowering
251 residents with knowledge and preventative measures to protect themselves
252 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

276 public health concern. Studies suggest that outbreak thresholds should be context-
277 specific, given the variability in transmission dynamics across different locations
278 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
279 Channel often base thresholds on 2 standard deviations (SD) above the mean
280 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
281 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
282 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
283 significantly across regions and time, making them inconsistent and incomparable.

284 From the studies above, this research implements an outbreak definition basing
285 the threshold on 2 standard deviations (SD) above the mean number of historic
286 dengue cases. It is important to note that for future outbreak definitions, addi-
287 tional local context like available hospital space etc., must be taken into account
288 for a more effective outbreak definition.

289 **2.3 Existing System: RabDash DC**

290 RabDash, developed by the University of the Philippines Mindanao, is a web-
291 based dashboard for rabies data analytics. It combines predictive modeling with
292 genomic data, enabling local health authorities to optimize interventions and al-
293 locate resources more effectively. RabDash’s modules include trend visualization,
294 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
295 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

296 For DengueWatch, RabDash serves as a strong inspiration, particularly in
297 its monitoring, historical trend visualization, and forecasting capabilities. These
298 features align well with the needs of dengue control efforts, providing real-time
299 insights into outbreak trends and enabling more effective, data-driven decision-
300 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
301 breaks similarly require time-series forecasting models. By using LSTM, RabDash
302 effectively models trends in outbreak data, which provides a framework for adapt-
303 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
304 form traditional methods, such as ARIMA and MLP, in handling the complexities
305 of time-dependent epidemiological data (Ligue & Ligue, 2022).

306 2.4 Deep Learning

307 The study of (Ligue & Ligue, 2022) highlights how data-driven models can help
308 predict dengue outbreaks. The authors compared traditional statistical meth-
309 ods, such as non-seasonal and seasonal autoregressive integrated moving average
310 (ARIMA), and traditional feed-forward network approach using a multilayer per-
311 ceptron (MLP) model with a deep learning approach using the long short-term
312 memory (LSTM) architecture in their prediction model. They found that the
313 LSTM model performs better in terms of accuracy. The LSTM model achieved a
314 much lower root mean square error (RMSE) compared to both MLP and ARIMA
315 models, proving its ability to capture complex patterns in time-series data (Ligue
316 & Ligue, 2022). This superior performance is attributed to LSTM’s capacity
317 to capture complex, time-dependent relationships within the data, such as those
318 between temperature, rainfall, humidity, and mosquito populations, all of which
319 contribute to dengue incidence (Ligue & Ligue, 2022).

320 2.5 Kalman Filter

321 The Kalman Filter is another powerful tool for time-series forecasting that can be
322 integrated into our analysis. It provides a recursive solution to estimating the state
323 of a linear dynamic system from a series of noisy measurements. Its application
324 in epidemiological modeling can enhance prediction accuracy by accounting for
325 uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters
326 are effective in predicting infectious disease outbreaks by refining estimates based
327 on observed data. A study published in *Frontiers in Physics* utilized the Kalman
328 filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman
329 filter effectively tracked the progression of deaths and cases, providing critical in-
330 sights for public health decision-making (Ahmadini et al., 2021). Another research
331 article in *PLOS ONE* focused on tracking the effective reproduction number (R_t)
332 of COVID-19 using a Kalman filter. This method estimated the growth rate of
333 new infections from noisy data, demonstrating that the Kalman filter could main-
334 tain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli,
335 Bullano, Kucinskas, & Rondón-Moreno, 2021).

336 Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM
337 models using our own collected dengue case data along with weather data to
338 identify the most effective model for real-time forecasting.

339 2.6 Weather Data

340 The relationship between weather patterns and mosquito-borne diseases is inher-
341 ently nonlinear, meaning that fluctuations in disease cases do not respond propor-
342 tionally to changes in climate variables(Colón-González, Fezzi, Lake, & Hunter,
343 2013) Weather data, such as minimum temperature and accumulated rainfall, are
344 strongly linked to dengue case fluctuations, with effects observed after several
345 weeks due to mosquito breeding and virus incubation cycles. Integrating these
346 lagged weather effects into predictive models can improve early warning systems
347 for dengue control(Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests
348 that weather-based forecasting models using variables like mean temperature and
349 cumulative rainfall can provide early warnings of dengue outbreaks with high sen-
350 sitivity and specificity, enabling predictions up to 16 weeks in advance(Hii, Zhu,
351 Ng, Ng, & Rocklöv, 2012).

352 We will utilize weather data, including variables such as temperature, rainfall,
353 and humidity, as inputs for our dengue forecasting model. Given the strong, non-
354 linear relationship between climate patterns and dengue incidence, these weather
355 variables, along with their lagged effects, are essential for enhancing prediction
356 accuracy and providing timely early warnings for dengue outbreaks.

357 2.7 Chapter Summary

358 This chapter reviewed key literature relevant to our study, focusing on existing
359 systems, predictive modeling techniques and the role of weather data in forecast-
360 ing dengue outbreaks. We examined systems like RabDash DC, which integrates
361 predictive modeling with real-time data to inform public health decisions, provid-
362 ing a foundational structure for our Dengue Watch System. Additionally, deep
363 learning approaches, particularly Long Short-Term Memory (LSTM) networks,
364 were highlighted for their effectiveness in time-series forecasting, while alternative
365 methods such as ARIMA and Kalman Filters were considered for their ability to
366 model complex temporal patterns and handle noisy data.

367 The literature further underscores the significance of weather variables—such
368 as temperature and rainfall—in forecasting dengue cases. Studies demonstrate
369 that these variables contribute to accurate outbreak prediction models. Lever-
370 aging these insights, our study will incorporate both weather data and historical
371 dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

3.1 Research Activities

3.1.1 Gather Dengue Data and Climate Data to Create a Complete Dataset for Forecasting

Acquisition of Dengue Case Data

The historical dengue case dataset used in this study was obtained from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD) via Freedom of Information (FOI) requests. The decision to use weekly intervals was driven by the need for precision and timeliness in capturing fluctuations in dengue cases and weather conditions. Dengue transmission is influenced by short-term changes in weather variables such as rainfall and temperature, which impact mosquito breeding and virus transmission cycles. A weekly granularity allowed the model to better capture these short-term trends, enabling more accurate predictions and responsive public health interventions.

Moreover, using a weekly interval provided more data points for training the models compared to a monthly format. This is particularly critical in time series modeling, where larger datasets help improve the robustness of the model and its ability to generalize to new data. Also, the collection of weather data was done by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall, temperature, and humidity) from Weather Underground (wunderground.com).

Data Fields

- **Time.** Represents the specific year and week corresponding to each entry in the dataset.
- **Rainfall.** Denotes the observed average rainfall, measured in millimeters, for a specific week.
- **Humidity.** Refers to the observed average relative humidity, expressed as a percentage, for a specific week.
- **Max Temperature.** Represents the observed maximum temperature, measured in degrees Celsius, for a specific week.
- **Average Temperature.** Represents the observed average temperature, measured in degrees Celsius, for a specific week.

- 415 • **Min Temperature.** Represents the observed minimum temperature, mea-
416 sured in degrees Celsius, for a specific week.
- 417 • **Wind.** Represents the observed wind speed, measured in miles per hour
418 (mph), for a specific week.
- 419 • **Cases.** Refers to the number of reported dengue cases during a specific
420 week.

421 **Data Integration and Preprocessing**

422 The dengue case data was integrated with the weather data to create a com-
423 prehensive dataset, aligning the data based on corresponding timeframes. The
424 dataset underwent a cleaning process to address any missing values, outliers, and
425 inconsistencies to ensure its accuracy and reliability. To ensure that all features
426 and the target variable were on the same scale, a MinMaxScaler was applied to
427 normalize both the input features (climate data) and the target variable (dengue
428 cases).

429 **Exploratory Data Analysis (EDA)**

- 430 • Analyzed trends, seasonality, and correlations between dengue cases and
431 weather factors.
- 432 • Created visualizations like time series plots and scatterplots to highlight
433 relationships and patterns in the data.

434 **Outbreak Detection**

435 To detect outbreaks, we computed the outbreak threshold value of dengue cases
436 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

437 where μ is the historical mean and σ is the standard deviation.

438 3.1.2 Develop and Evaluate Deep Learning Models for 439 Dengue Case Forecasting

440 The deep learning models were developed and trained to forecast weekly dengue
441 cases using historical weather data (rainfall, temperature, wind, and humidity)
442 and dengue case counts. The dataset was normalized and divided into training and
443 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
444 for preparing and training the model are outlined below.

445 Data Preprocessing

446 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
447 ture, wind, humidity) and dengue case counts. The "Time" column was converted
448 to a datetime format to ensure proper temporal indexing. To standardize the data
449 for training, MinMaxScaler was employed, normalizing the feature values and tar-
450 get variable to a range of 0 to 1. This step ensured that the models could efficiently
451 process the data without being biased by feature scaling differences.

452 LSTM Model

453 The dataset was split into training and test sets to evaluate the model's perfor-
454 mance and generalizability:

- 455 • **Training Set:** 80% of the data (572 sequences) was used for model training,
456 enabling the LSTM to learn underlying patterns in historical dengue case
457 trends and their relationship with weather variables.
- 458 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
459 testing

460 To prepare the data for LSTM, a sliding window approach was utilized. Se-
461 quences of weeks of normalized features were constructed as input, while the
462 dengue case count for the subsequent week was set as the target variable. This
463 approach ensured that the model leveraged temporal dependencies in the data for
464 forecasting. To enhance the performance of the LSTM model in predicting dengue
465 cases, Bayesian Optimization was employed using the Keras Tuner library. The
466 tuning process aimed to minimize the validation loss (mean squared error) by
467 adjusting key model hyper-parameters. The search space is summarized below:

468 **LSTM units:**

- 469 • min value: 32
- 470 • max value: 128
- 471 • step: 16
- 472 • sampling: linear

473 **Learning Rate:**

- 474 • min value: 0.0001
- 475 • max value: 0.01
- 476 • step: None
- 477 • sampling: log

478 The tuner was instantiated with:

- 479 • **max trials = 10:** Limiting the search to 10 different configurations
- 480 • **executions per trial = 3:** Running each configuration thrice to reduce
481 variance
- 482 • **validation split = 0.2:** Reserving 20% of the training data for validation

483 The hyperparameter tuning was conducted for three different window sizes of
484 data: 5, 10, and 20. This allows the model to have the optimal hyperparameters
485 used for each window size. Training was conducted over 100 epochs with early
486 stopping to prevent overfitting while maintaining computational efficiency. A
487 batch size of 1 was used, enabling the model to process individual sequences,
488 which is suitable for smaller datasets but results in longer training times. The
489 Adam optimizer, known for its adaptive learning capabilities and stability was
490 employed.

491 To validate the effectiveness of the model, cross-validation was implemented.
492 However, standard k-fold cross-validation randomly shuffles the data, which isn't
493 suitable for time series since the order of observations is important. To address
494 this, a time series-specific cross-validation strategy was used with TimeSeriesS-
495 plit from the scikit-learn library. This method creates multiple train-test splits

496 where each training set expands over time and each test set follows sequentially.
497 This approach preserves the temporal structure of the data while helping reduce
498 overfitting by validating the model across different time segments.

499 After training, predictions on both the training and test datasets were rescaled
500 to their original scale using the inverse transformation of MinMaxScaler. Model
501 performance was evaluated using the mean squared error (MSE), root mean
502 squared error (RMSE) and mean absolute error (MAE).

503 **ARIMA**

504 The ARIMA model was utilized to forecast weekly dengue cases, leveraging histor-
505 ical weather data—including rainfall, maximum temperature, and humidity—as
506 exogenous variables alongside historical dengue case counts as the primary depen-
507 dent variable. The dataset was partitioned into training (80%) and testing (20%)
508 sets while maintaining temporal consistency.

509 To identify the optimal ARIMA configuration, a comprehensive grid search
510 was performed across the following parameter ranges:

- 511 • Autoregressive order (p): 0 to 3
- 512 • Differencing order (d): 0 to 2
- 513 • Moving average order (q): 0 to 3

514 Each combination of (p,d,q) was used to fit an ARIMA model, and perfor-
515 mance was evaluated based on the mean squared error (MSE) between the pre-
516 dicted and actual dengue cases on the test set. The parameter set that achieved
517 the lowest MSE was selected as the final model configuration.

518 Following model selection, the best-fit ARIMA model was retrained on the
519 training set and subsequently used to forecast dengue cases for the test period.
520 The predictions were assigned to the **PredictedCases** column in the test dataset.
521 Model performance was further assessed using key evaluation metrics, including
522 MSE, root mean squared error (RMSE), and mean absolute error (MAE). Visual
523 comparisons between actual and predicted dengue cases were produced through
524 line plots to better illustrate the model’s forecasting accuracy.

525 Seasonal ARIMA (SARIMA)

526 The SARIMA modeling process began with data preprocessing, which included
527 handling missing values through interpolation or imputation, and standardizing
528 features to ensure stable model training. The dataset was then split into training
529 and testing sets in an 80:20 ratio, preserving the temporal order of observations.
530 Seasonality analysis was conducted using time series decomposition and autocor-
531 relation plots, which revealed a periodicity of 52 weeks—justifying the adoption
532 of a seasonal model. To fine-tune the model, a grid search was performed over a
533 range of SARIMA parameters $(p,d,q)(P,D,Q)[S]$, while stationarity was validated
534 using the Augmented Dickey-Fuller (ADF) test. The model was then trained
535 on the dataset using rainfall, temperature, and humidity as exogenous variables,
536 with convergence ensured by setting a maximum number of iterations. Residual
537 diagnostics were used to confirm that residuals were uncorrelated, indicating a
538 good model fit. For evaluation, forecasts were compared against actual values,
539 and results were visualized with line plots. Finally, to validate the model’s gener-
540 alizability across different time periods, Time Series Cross-Validation with three
541 folds was applied. This allowed assessment of the model’s performance on multi-
542 ple time segments, providing insights into its robustness in real-world forecasting
543 scenarios.

544 Kalman Filter:

- 545 • Input Variables: The target variable (Cases) was modeled using three re-
546 gressors: rainfall, max temperature, and humidity.
- 547 • Training and Testing Split: The dataset was split into 80% training and
548 20% testing to evaluate model performance.
- 549 • Observation Matrix: The Kalman Filter requires an observation matrix,
550 which was constructed by adding an intercept (column of ones) to the re-
551 gressors.

552 The Kalman Filter’s Expectation-Maximization (EM) method was employed
553 for training, iteratively estimating model parameters over 10 iterations. After
554 training, the smoothing method was used to compute the refined state estimates
555 across the training data. Observation matrices for the test data were constructed
556 in the same manner as for the training set, ensuring compatibility with the learned
557 model parameters. On the test data, the Kalman Filter applied these parameters
558 to predict and correct the estimated dengue cases, providing more stable and
559 accurate forecasts compared to direct regression models. Additionally, a hybrid

560 Kalman Filter–LSTM (KF-LSTM) model was developed to combine the strengths
561 of both approaches. In this setup, the LSTM model was first used to predict
562 dengue cases based on historical data and weather features. The Kalman Filter
563 was then applied as a post-processing step to the LSTM predictions, smoothing
564 out noise and correcting potential errors.

565 **3.1.3 Integrate the Predictive Model into a Web-Based** 566 **Data Analytics Dashboard**

567 **Dashboard Design and Development**

- 568 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 569 – Interactive visualizations of yearly dengue case trends.
 - 570 – Data input and update forms for dengue and weather data.
 - 571 – Map display of dengue cases in each district in Iloilo City

572 **Model Integration and Deployment**

- 573 • Deploy the best-performing model within the dashboard as a backend service
574 to enable real-time or periodic forecasting.

575 **3.1.4 System Development Framework**

576 The Agile Model is the birthchild of both iterative and incremental approaches
577 in Software Engineering. It aims to be flexible and effective at the same time by
578 being adaptable to change. It's also important to note that small teams looking
579 to construct and develop projects quickly can benefit from this kind of method-
580 ology. As the Agile Method focuses on continuous testing, quality assurance is a
581 guarantee since bugs and errors are quickly identified and patched.

582 **Design and Development**

583 After brainstorming and researching the most appropriate type of application to
584 accommodate both the prospected users and the proposed solutions, the team
585 has decided to proceed with a web application. Given the time constraints and
586 available resources, it has been decided that the said means is the most pragmatic

587 and practical move. The next step is to select modern and stable frameworks
 588 that align with the fundamental ideas learned by the researchers in the university.
 589 The template obtained from WVCHD and Iloilo Provincial Epidemiology and
 590 Surveillance Unit was meticulously analyzed to create use cases and develop a
 591 preliminary well-structured database that adheres to the requirements needed
 592 to produce a quality application. The said use cases serve as the basis of general
 593 features. Part by part, these are converted into code, and with the help of selected
 594 libraries and packages, it resulted in the desired outcome that may still modified
 595 and extended to achieve scalability.

596 Testing and Integration

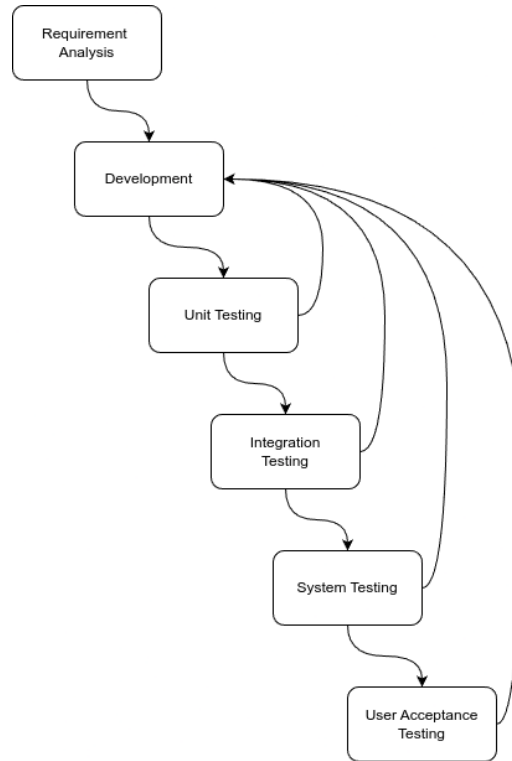

Figure 3.2: Testing Process for DengueWatch

597 Implementing testing is important to validate the system's performance and ef-
 598 ficacy. Thus a series of tests were conducted to identify and resolve bugs during
 599 the developmental phase. Each feature was rigorously tested to ensure quality as-
 600 surance, with particular emphasis on prerequisite features, as development cannot
 601 progress properly if these fail. Because of this, integration between each feature

602 serves as a pillar for a cohesive user experience. Since dengue reports include
603 confidential information, anonymized historical dengue reports were used to train
604 the model and create the foundational architecture of the system. By using func-
605 tional tests, data validation and visualization can be ensured for further continual
606 improvements. Security testing is also important as it is needed to safeguard
607 confidential information when the system is deployed. It includes proper authen-
608 tication, permission views, and mitigating common injection attacks. Finally, a
609 user acceptance test from the prospected users, in this case, doctors, nurses, and
610 other health workers is crucial to assess its performance and user experience. It
611 enables the developers to confirm if the system meets the needs of the problem.

612 **3.2 Development Tools**

613 **3.2.1 Software**

614 **Github**

615 GitHub is a cloud-based platform that tracks file changes using Git, an open-
616 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
617 used in the project to store the application’s source code, manage the system’s
618 source version control, and serve as a repository for the Latex files used in the
619 actual research.

620 **Visual Studio Code**

621 Visual Studio Code is a free, lightweight, and cross-platform source code editor
622 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
623 this project’s programming and scripting languages, it was chosen as the primary
624 source code editor.

625 **Django**

626 Django is a free and open-sourced Python-based web framework that offers an
627 abstraction to develop and maintain a secure web application. As this research
628 aims to create a well-developed and maintainable application, it is in the best
629 interest to follow an architectural pattern that developers and contributors in the

630 future can understand. Since Django adheres to Model-View-Template (MVT)
631 that promotes a clean codebase by separating data models, business logic, and
632 presentation layers, it became the primary candidate for the application’s back-
633 bone.

634 **Next.js**

635 A report by Statista (2024) claims that React is the most popular front-end frame-
636 work among web developers. However, React has limitations that can be a nui-
637 sance in rapid software development, which includes routing and performance op-
638 timizations. This is where Next.js comes in—a framework built on top of React.
639 It offers solutions for React’s deficiency, making it a rising star in the framework
640 race.

641 **Postman**

642 As the application heavily relies on the Application Programming Interface (API)
643 being thrown by the backend, it is a must to use a development tool that facilitates
644 the development and testing of the API. Postman is a freemium API platform
645 that offers a user-friendly interface to create and manage API requests (*What is*
646 *Postman? Postman API Platform*, n.d.).

647 **3.2.2 Hardware**

648 The web application was developed on laptop computers with minimum specifica-
649 tions of an 11th-generation Intel i5 CPU and 16 gigabytes of RAM. Furthermore,
650 an RTX 3060 mobile GPU was also utilized to retrain the integrated model locally.

651 **3.2.3 Packages**

652 **Django REST Framework**

653 Django Rest Framework (DRF) is a third-party package for Django that provides a
654 comprehensive suite of features to simplify the development of robust and scalable
655 Web APIs (Christie, n.d.). These services include Serialization, Authentication
656 and Permissions, Viewsets and Routers, and a browsable API .

657 Leaflet

658 One of the features of the web application is the ability to map the number
659 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
660 most importantly, stable JavaScript package that can do the job. With its ultra-
661 lightweight size, it offers a comprehensive set of features that does not trade
662 off performance and usability (*Leaflet — an open-source JavaScript library for*
663 *interactive maps*, n.d.).

664 Chart.js

665 Another feature of the application is to provide users with informative, approach-
666 able data storytelling that is easy for everyone to understand. The transformation
667 of pure data points and statistics into figures such as charts is a big factor. Thus,
668 there is a need for a package that can handle this feature without compromising
669 the performance of the application. Chart.js is a free and open-source JavaScript
670 package that is made to meet this criteria as it supports various types of charts
671 (*Chart.js*, n.d.).

672 Tailwind CSS

673 Using plain CSS in production-quality applications can be counterproductive.
674 Therefore, CSS frameworks were developed to promote consistency and accelerate
675 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
676 which offers low-level utility classes that can be applied directly to each HTML
677 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
678 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
679 project, using this framework is a wise choice due to its stability and popularity
680 among developers.

681 Shadcn

682 Shadcn offers a collection of open-source UI boilerplate components that can be
683 directly copied and pasted into one's project. With the flexibility of the provided
684 components, Shadcn allows developers to have full control over customization and
685 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
686 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

687 **Zod**

688 Data validation is integral in this web application since it will handle crucial data
689 that will be used for analytical inferences and observations. Since Zod is primarily
690 used for validating and parsing data, it ensures proper communication between
691 the client and the server (Zod, n.d.).

692 3.3 Application Requirements

693 3.3.1 Backend Requirements

694 Database Structure Design

695 Determining how data flows and how it would be structured is crucial in creating
 696 the system as it defines how extendible and flexible it would be for future features
 697 and updates. Thus, creating a comprehensive map of data ensures proper nor-
 698 malization that eliminates data redundancy and improves data integrity. Figure
 699 3.3 depicts the designed database schema that showcases the relationship between
 700 the application's entities.

Figure 3.3: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

3.3.2 User Interface Requirements

Disease Reporting Unit Admin Interface

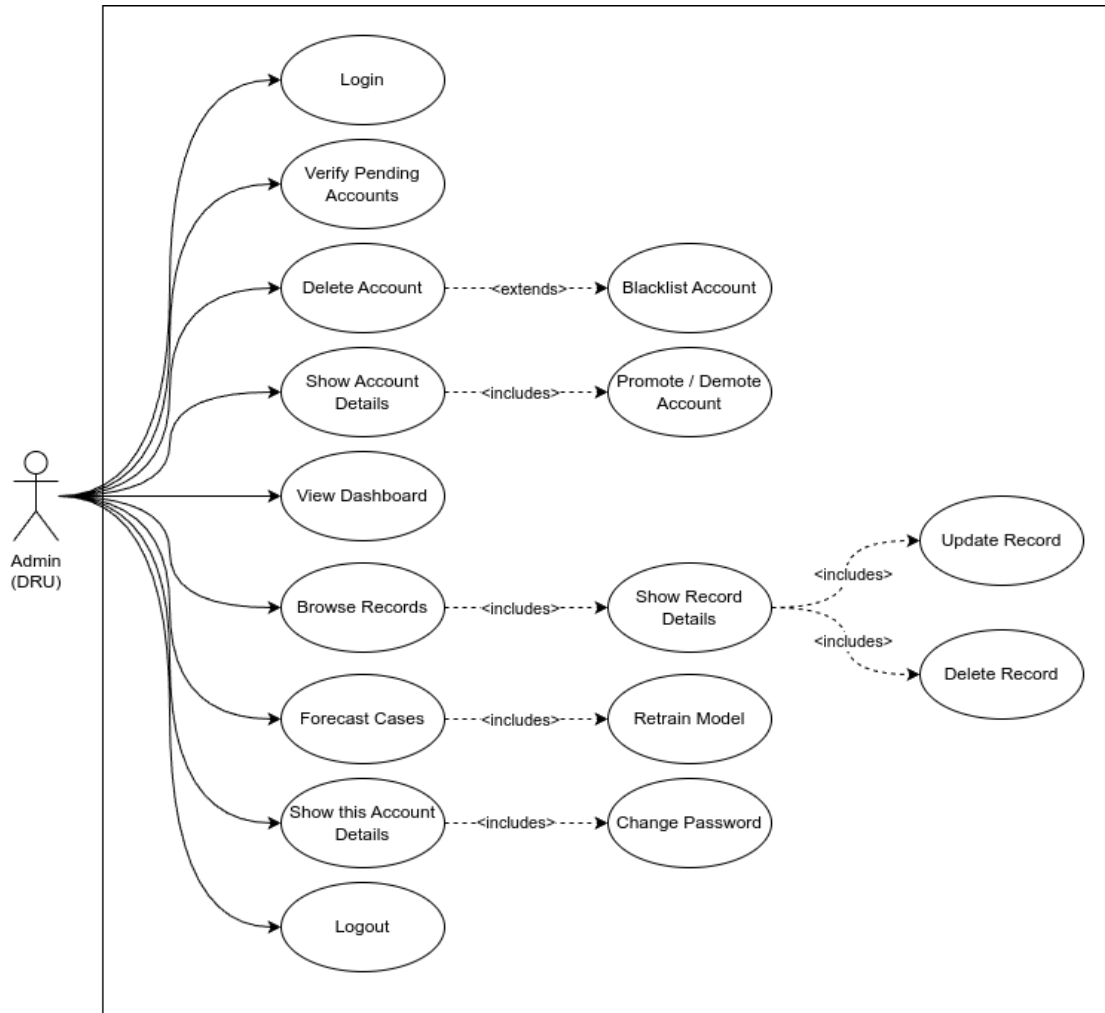

Figure 3.4: Use Case Diagram for DRU Admin

Surveillance Unit Admin Interface

Figure 3.4 shows the actions an admin for a specific Disease Reporting Unit (DRU) can take in the application. These include managing accounts, browsing records, and forecasting and retraining all the consolidated data under the unit. To protect the integrity of data, encoders that register to a DRU must first be verified by these users, and then the encoder's account can only be authorized to use the

709 application.

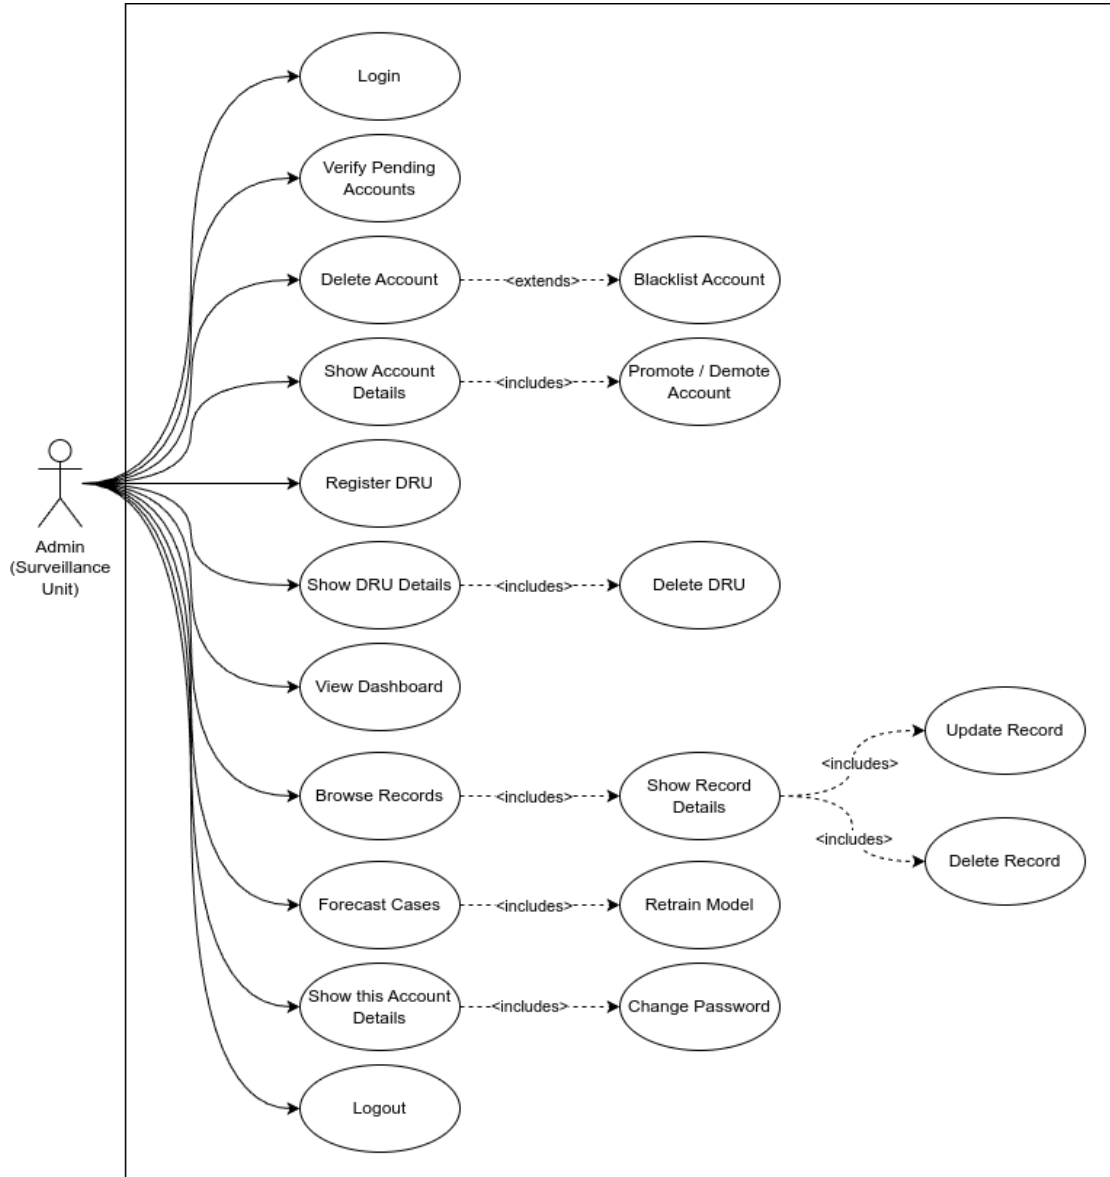

Figure 3.5: Use Case Diagram for Surveillance Unit Admin

710 While the previous use case focuses on hospitals, clinics, and other reporting
711 units, the use case presented in Figure 3.5 has a one-step higher authorization as
712 it manages these DRUs. It has the same features as the DRU admin but with
713 extra management of the DRUs under a specific surveillance unit. At this point,
714 only the authorized surveillance unit administrator can register and create a DRU
715 to uphold transparency and accountability.

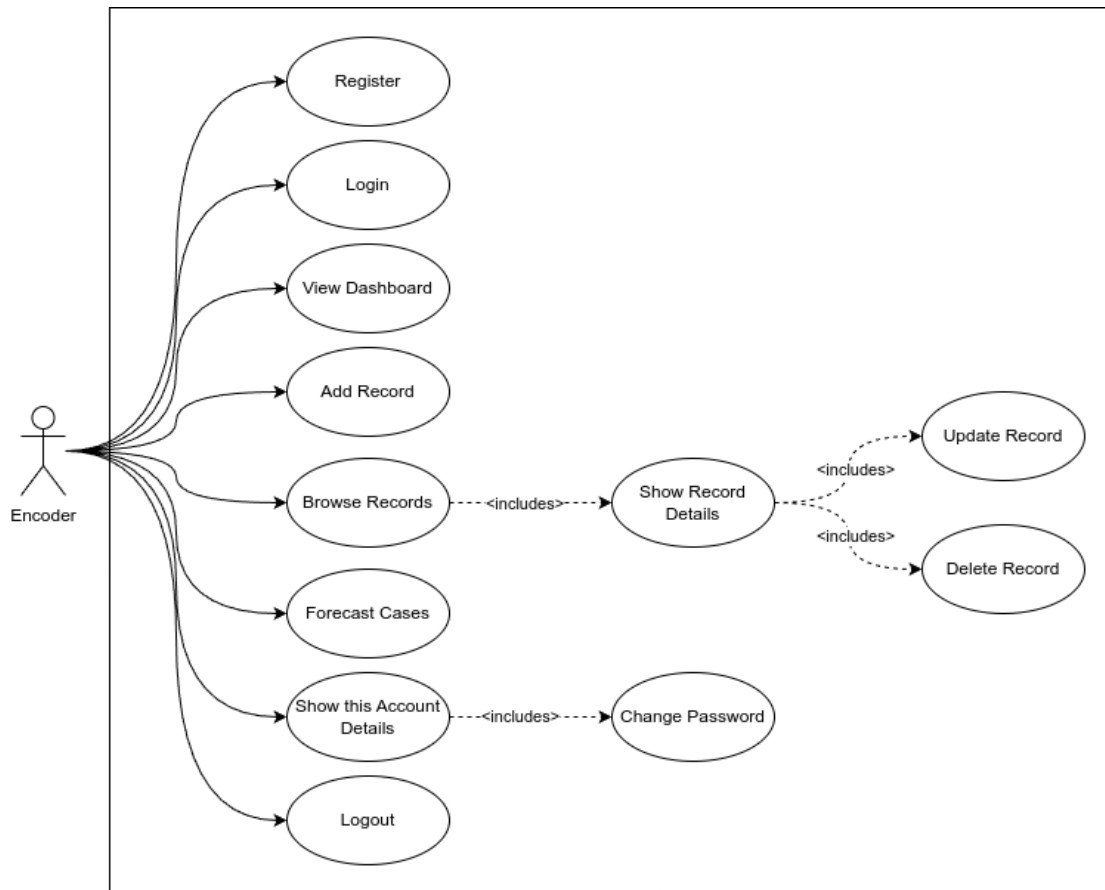

Figure 3.6: Use Case Diagram for Encoder

Figure 3.6, on the other hand, illustrates the use cases for the system's primary users. These users can register but must wait for further verification to access the application. Similar to the previous interfaces, encoders can browse and manage records, as well as forecast the consolidated cases under a specific surveillance or disease reporting unit, but they are not allowed to retrain the model. Lastly, they are the only type of user that can file and create dengue cases by filling out a form with the required details.

724 3.3.3 Security and Validation Requirements

725 Password Encryption

726 Storing passwords as plain text in the database is a disgrace and a mortal sin in
727 production. It is important to implement precautionary methods such as hashing
728 and salting, followed by encryption with a strong algorithm, to prevent bad actors
729 from using the accounts for malicious transactions. By default, Django generates
730 a unique random salt for each password and encrypts it with Password-Based Key
731 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
732 techniques ensures that in the event of a data breach, cracking these passwords
733 would be time-consuming and useless for the attackers.

734 Authentication

735 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
736 the mechanism operates in a stateless manner, tokens are served only after a
737 successful login, eliminating the need for the server to keep a record of the token,
738 which is vulnerable to session hijacking. In addition, these tokens are signed with
739 a secret key, ensuring they have not been tampered with.

740 Data Validation

741 Both the backend and frontend should validate the input from the user to preserve
742 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
743 from the user. By doing this, the user can only send proper requests to the server
744 which streamlines the total workflow. On the other hand, Django has also a built-
745 in validator that checks the data type and ensures that the input matches the
746 expected format on the server side. These validation processes ensure that only
747 valid and properly formatted data is accepted, which reduces the risk of errors
748 and ensures consistency across the web application.

749 3.4 Calendar of Activities

750 A Gantt chart showing the schedule of the activities is included below. Each
751 bullet represents approximately one week of activity.

Table 3.1: Timetable of Activities for 2024

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. Dengue Case Data: The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. Weather Data: Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

```

770 4.2 Exploratory Data Analysis

771 From the summary above, the dataset consists of 720 weekly records with 8
772 columns:

- 773 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 774 • **Rainfall.** Weekly average rainfall (mm)
- 775 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
776 temperature data (C)
- 777 • **Wind.** Wind speed (m/s)
- 778 • **Humidity.** Weekly average humidity (%)
- 779 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases

std	NaN	35.448846	2.616379	0.999800	1.291659	2.446703	2.831674	37.144813

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks. To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

792 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 793 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

794

795 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 796 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 797 dengue cases. Notably, peak cases are observed during certain periods approx-
 798 imately 3 years, potentially aligning with specific climatic conditions such as
 799 increased rainfall or temperature changes. This underscores the importance of
 800 incorporating climate variables into the forecasting model.

801 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 802 and selected features, including rainfall, humidity, maximum temperature, aver-
 803 age temperature, minimum temperature, and wind speed. Among these, rainfall
 804 exhibits the highest positive correlation with dengue cases (correlation coefficient
 805 0.13), indicating that increased rainfall may contribute to higher cases counts.
 806 This aligns with existing studies suggesting that stagnant water from heavy rain-
 807 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 808 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 809 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 810 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 811 relationship than average and minimum temperature.

812 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 813 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

4.3 Outbreak Detection

To identify outbreaks, we calculated the outbreak threshold value using the historical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

where μ is the historical mean and σ is the standard deviation.

This result indicates that dengue cases exceeding 98 in Iloilo City can be considered an outbreak. However, it is important to note that this threshold serves only as a baseline. Additional parameters, such as the number of hospital beds available in the city, must be considered to compute a more effective threshold and develop an appropriate response strategy.

828 4.4 Model Training Results

829 The models were evaluated using three metrics: MSE, RMSE, and MAE. The
 830 table below provides a summary and comparative analysis of each model's results
 831 across these metrics, offering insights into the strengths and limitations of each
 832 forecasting technique for dengue case prediction in Iloilo City. The lower values
 833 of the three metrics indicate better forecasting performance. Table 4.1 shows that
 834 the models performed differently on testing data. LSTM outperformed the other
 835 models with the lowest RMSE, MSE, and MAE while the other three models had
 836 relatively higher values for the three metrics.

Method	LSTM	Seasonal ARIMA	ARIMA	Kalman Filter	KF-LSTM
Testing MSE	285.54	1261.20	1521.48	1474.82	785.35
Testing RMSE	16.90	34.45	39.00	38.40	25.56
Testing MAE	9.45	18.73	25.80	22.33	14.55
Best Parameters	Window Size: 5 Learning Rate: 0.01 Units: 64	(2,0,2)(0,1,1)	(1,2,2)	Observation Covariance: 10.0 Transition Covariance: $0.1 \times \text{Identity}$	Same as LSTM

Table 4.1: Comparison of different models for dengue prediction

837 4.4.1 LSTM Model

838 The LSTM model was tuned for the following parameters: learning rate and units.
 839 The hyperparameter tuning was conducted for each window size, finding the best
 840 parameters for each window size. Further evaluating which window size is most
 841 suitable for the prediction model, Table 4.2 shows the evaluation metrics for each
 window size used in the LSTM model training.

Window Size	MSE	RMSE	MAE	R ²
5	285.54	16.90	9.45	0.83
10	334.63	18.29	9.85	0.80
20	294.85	17.17	9.35	0.83

Table 4.2: Comparison of Window Sizes

842

843 The results indicate that a window size of 5 weeks provides the most accurate
 844 predictions, as evidenced by the lowest MSE and RMSE values. Furthermore, the
 845 R² score of 0.83 indicates that 83% of the variability in the target variable (cases)
 846 is explained by the independent variables (the inputs) in the model, making it a
 847 reliable configuration overall.

848 Figure 4.9 illustrates the model's performance in predicting dengue cases for
 849 each fold using a window size of 5. As shown in the plot, the training set progres-

850 sively increases with each fold, mimicking a real-world scenario where more data
851 becomes available over time for dengue prediction. Figure 4.10 demonstrates that
852 the predicted cases closely follow the trend of the actual cases, indicating that the
853 LSTM model successfully captures the underlying patterns in the data. It is also
854 evident that as the fold number increases and the training set grows, the accuracy
855 of the predictions on the test set improves. Despite the test data being unseen,
856 the model exhibits a strong ability to generalize, suggesting it effectively leverages
857 past observations to predict future trends.

Figure 4.9: Training Folds - Window Size 5

Figure 4.10: Testing Folds - Window Size 5

858 4.4.2 ARIMA Model

Figure 4.11: ARIMA Prediction Results for Test Set

859 The ARIMA model was developed to capture non-seasonal trends in the data.
 860 To determine the best model configuration, grid search was used to explore vari-
 861 ous combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**.
 862 The model was iteratively refined over **400 iterations** to ensure convergence to
 863 an optimal solution. Figure 4.11 illustrates the comparison between actual and
 864 predicted dengue cases in the test set. As shown in the plot, the ARIMA model
 865 struggled to capture the non-linear characteristics and abrupt spikes in the data.
 866 Consequently, it failed to accurately reflect the fluctuations and outbreak patterns
 867 seen in the actual case counts.

868 The model's performance was assessed using regression metrics to evaluate its
 869 forecasting capability. The ARIMA model yielded the following error metrics:

- 870 • **MSE (Mean Squared Error):** 1521.48
- 871 • **RMSE (Root Mean Squared Error):** 39.01
- 872 • **MAE (Mean Absolute Error):** 25.80

4.4.3 Seasonal ARIMA (SARIMA) Model

To address the limitations of the ARIMA model, a Seasonal ARIMA (SARIMA) model was developed to capture both non-seasonal and seasonal variations in the data.

Figure 4.12: Seasonal ARIMA Prediction Results for Test Set

This model incorporates seasonal parameters, which were tuned using grid search to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA, **400 iterations** were applied to ensure a robust fit. As shown in Figure 4.12, the SARIMA model demonstrates a notable improvement in performance. Unlike its non-seasonal counterpart, it effectively captures the general trend and aligns more closely with the peaks observed in the actual dengue cases, indicating its ability to model seasonal dynamics.

The model's performance was assessed using regression metrics to evaluate its forecasting capability. The SARIMA model yielded the following error metrics:

- **MSE:** 1109.69
- **RMSE:** 33.31

888

- **MAE: 18.09**

889
890
891
892

The lower error values, when compared to the ARIMA model, highlight the SARIMA model's superior capability in forecasting dengue cases. Its effectiveness in capturing seasonal patterns contributed to a more accurate representation of the actual cases.

893
894
895
896
897
898

After training the model, the SARIMA model was validated using the same Time Series Cross-Validation strategy employed in the LSTM model. Table 4.3 presents the performance metrics for each fold, as well as the average metrics across all folds. The average RMSE and MAE values were close to those obtained during the initial training phase, indicating that the SARIMA model performed consistently across different time segments.

Fold	MSE	RMSE	MAE
1	659.68	25.68	16.00
2	2127.49	46.12	21.30
3	996.43	31.56	18.89
Average	1261.20	34.45	18.73

Table 4.3: Comparison of SARIMA performance for each fold

899

4.4.4 Kalman Filter Model

900
901
902
903
904
905
906
907

Figure 4.13 shows the comparison between the actual dengue cases and the predicted values on the test set. As illustrated in the plot, the Kalman Filter model demonstrates a moderate ability to follow the general trend of the actual data. While it effectively captures some rising and falling patterns, it still struggles to accurately replicate the sharp peaks and extreme values found in the real case counts. This limitation is particularly noticeable during the large spikes in 2022 and 2024. The model's performance was evaluated using standard regression metrics. The results are as follows:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

Figure 4.13: Kalman Filter Prediction Results for Test Set

908 The Kalman Filter was then combined with the LSTM model in order to see
 909 improvements in its predictions. Table 4.4 shows the metrics across three folds
 910 using the same Time Series Cross Validation Strategy employed in the previous
 911 models to see how it performed on different time segments.

Fold	MSE	RMSE	MAE
1	113.59	10.66	6.42
2	752.51	27.43	12.11
3	1489.95	38.60	25.13
Average	785.35	25.56	14.55

Table 4.4: Comparison of KF-LSTM performance for each fold

912 2

913 As can be seen in the table above, the performance of the hybrid model demon-
 914 strated improvements in all metrics as compared to just using the Kalman Filter
 915 alone.

916 4.5 System Prototype

917 4.5.1 Home Page

918 The Home Page is intended for all visitors of the web application. The Analytics
 919 Dashboard, which displays relevant statistics for dengue cases at a certain year
 920 and location, is the primary component highlighted, as seen in Figure 4.14. This
 921 component includes a combo chart that graphs the number of dengue cases and
 922 deaths per week in a specific year, a choropleth map that tracks the number of
 923 dengue cases per location, and various bar charts that indicate the top locations
 924 affected by dengue.

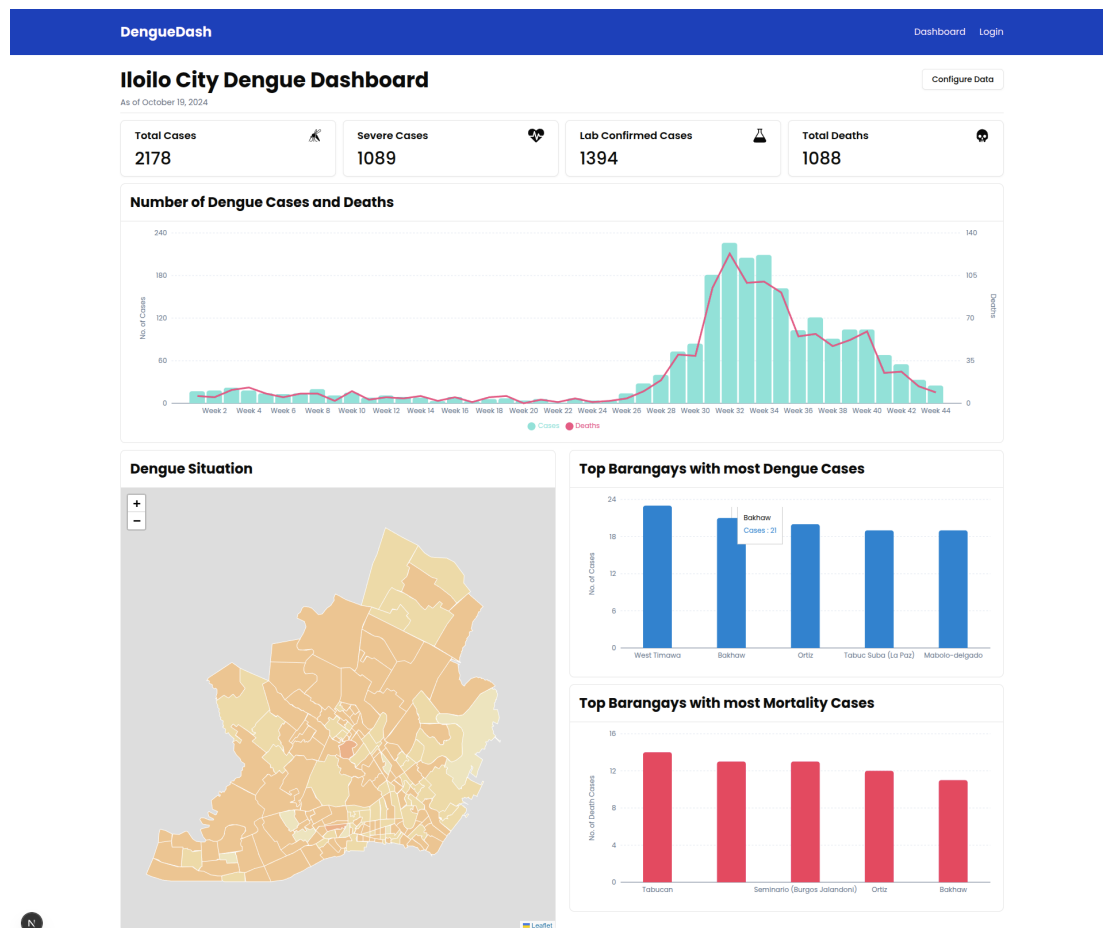

Figure 4.14: Home Page

4.5.2 User Registration, Login, and Authentication

The registration page, as shown in Figure 4.15, serves as a gateway to access the authenticated pages of the web application. Only prospected encoders can create an account since administrator accounts are only made by existing administrator accounts to protect the data's integrity in production. After registering, the "encoder account" cannot access the authorized pages yet as it needs to be verified first by an administrator managing the unit the user entered. Once verified, the user can log in to the system through the page shown in Figure 4.16. After entering the correct credentials, which consist of an email and password, the system uses HTTP-only cookies containing JSON Web Tokens (JWT) to prevent vulnerability to Cross-site Scripting (XSS) attacks. It will then proceed to the appropriate page the type of user belongs to.

937 4.5.3 Personnel Interface

938 Encoder's View

939 Figures 4.17 and 4.18 show the digitized counterpart of the form obtained from the
 940 Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to sup-
 941 port expandability for future features, some fields were modified to accommodate
 942 more detailed input. It is worth noting that all of the included fields adhere to the
 943 latest Philippine Integrated Disease and Surveillance Response (PIDSRS) Dengue
 944 Forms, which the referenced form was based on. By doing this, it is assumed
 945 that the targeted users will have a familiarity when deployed on a national scale.
 946 On a further note, the case form includes the patient's basic information, dengue
 947 vaccination status, consultation details, laboratory results, and the outcome.

Figure 4.18: Second Part of Case Report Form

948 Once the data generated from the case report form is validated, it will be
 949 assigned as a new case and can be accessed through the Dengue Reports page, as
 950 shown in Figure 4.19. The said page displays basic information about the patient
 951 related to a specific case, including their name, address, date of consultation, and
 952 clinical and case classifications. It is also worth noting that it only shows cases
 953 the user is permitted to view. For example, in a local Disease Reporting Unit
 954 (DRU) setting, the user can only access records that came from the same DRU.
 955 On the other hand, in a consolidated surveillance unit such as a regional and
 956 provincial quarter, its users can view all the records that came from all the DRUs
 957 that report to them. Moving forward, Figure 4.20 shows the detailed case report
 958 of the patient on a particular consultation date.

The screenshot displays the DengueDash application interface. On the left is a sidebar menu with the following items: Analytics, Forms, Data Tables (expanded to show Dengue Reports and Another Report), and Settings. The main content area is titled 'Building Your Application > Data Fetching' and contains a table of dengue reports. The table has columns for Case ID, Name, Barangay, City, Date Consulted, Clinical Classification, Case Classification, and Action. There are 12 rows of data, each with an 'Open' button in the Action column. At the bottom of the table is a pagination control showing '1' of 218 items.
