Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This research focused on developing a centralized system for monitoring and forecasting dengue trends in Iloilo City, incorporating graphical visualizations such as heatmaps, trends, and historical graphs. The study explored the application of artificial intelligence (AI) in dengue prediction, utilizing deep learning models. The performance of the Long Short-Term Memory (LSTM) model was compared with traditional statistical methods, including non-seasonal and seasonal Autoregressive Integrated Moving Average (ARIMA) models and the Kalman Filter. Evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) were used to identify the most effective model for integration into the system. Forecasting was based on climate variables such as temperature, rainfall, relative humidity, and previous monthly case counts. The LSTM model emerged as the best performer with an RMSE of 16.15, demonstrating its suitability for time-series predictions, while the Kalman Filter showed the poorest performance with an RMSE of 38.40. By integrating predictive analytics with real-time data visualization, the proposed system aims to support public health agencies, such as the Department of Health (DOH), by providing actionable insights for proactive intervention strategies. This AI-driven solution enhances traditional outbreak reporting systems by enabling timely, data-informed decisions to mitigate the impact of dengue in the region.

Keywords: ARIMA, artificial intelligence, dengue prediction, LSTM, Kalman Filter, deep learning, climate variables, public health, outbreak mitigation

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

156 This study explores the monitoring and forecasting of dengue outbreaks by an-
157 alyzing key factors such as temperature, relative humidity, and historical dengue
158 cases, using different models. The findings aim to provide an advanced, AI-driven
159 alternative for dengue prevention and control, targeting agencies like the Depart-
160 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
161 in Iloilo City, this research aspires to improve outbreak responses through cutting-
162 edge technology rather than traditional reporting methods.

163 1.2 Problem Statement

164 Dengue remains a critical public health challenge worldwide, with cases increasing
165 due to the easing of COVID-19 restrictions and heightened global mobility. While
166 a temporary decline in cases was observed during the pandemic (2020–2022) due
167 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
168 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
169 regions like the Philippines, the threat is particularly severe. In Iloilo City and
170 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
171 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
172 pital beds occupied by dengue patients, highlighting the urgent need for effective
173 predictive tools. The lack of a reliable system to monitor and forecast dengue
174 outbreaks contributes to delayed interventions, exacerbating public health risks
175 and healthcare burdens in the region.

176 1.3 Research Objectives

177 1.3.1 General Objective

178 This study aims to develop an AI-based dengue forecasting and monitoring system
179 for Iloilo City and Province. The researchers will train and compare multiple deep
180 learning models to predict dengue case trends based on climate data and historical
181 dengue cases to help public health officials in possible dengue case outbreaks.

182 1.3.2 Specific Objectives

183 Specifically, this study aims to:

- 184 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
185 (including temperature, rainfall, wind, and humidity) from online sources.
186 Combine and aggregate these data into a unified dataset to facilitate com-
187 prehensive dengue case forecasting.
- 188 2. Evaluate deep learning models for predicting dengue cases using metrics
189 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
190 and Mean Squared Error (MSE). Compare the performance of these models
191 to determine the most accurate forecasting approach.
- 192 3. Develop a web-based analytics dashboard that integrates a predictive model
193 and provides data management system for dengue cases in Iloilo City and
194 the Province.
- 195 4. Assess the usability and effectiveness of the analytics dashboard through
196 structured feedback and surveys involving health professionals and policy-
197 makers.

198 1.4 Scope and Limitations of the Research

199 This study aims to gather dengue data from the Iloilo Provincial Health Office
200 and climate data from online sources such as PAGASA or weatherandclimate.com.
201 These data will be preprocessed, cleaned, and combined into a unified dataset to
202 facilitate comprehensive dengue case forecasting. However, the study is limited by
203 the availability and completeness of historical data. Inconsistent or missing data
204 points may introduce biases and reduce the quality of predictions. Furthermore,
205 the granularity of the data will be in a weekly format.

206 To evaluate deep learning models for predicting dengue cases, the study will
207 train and compare the performance of various models, using metrics like Mean
208 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
209 aim to provide accurate forecasts, their performance is heavily influenced by the
210 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
211 predictions. Additionally, the models cannot fully account for external factors
212 such as public health interventions or socio-economic conditions which may impact
213 dengue transmission dynamics.

214 The study also involves developing a web-based analytics dashboard that in-
215 tegrates predictive models and provides a data management system for dengue
216 cases in Iloilo City and the Province. This dashboard will offer public health
217 officials an interactive interface to visualize dengue trends, input new data, and

218 identify risk areas. However, its usability depends on feedback from stakeholders,
219 which may vary based on their familiarity with analytics tools. Moreover, exter-
220 nal factors such as limited internet connectivity or device availability in remote
221 areas may affect the system’s adoption and effectiveness. While the dashboard
222 provides valuable insights, it cannot incorporate all factors influencing dengue
223 transmission, emphasizing the need for ongoing validation and refinement.

224 1.5 Significance of the Research

225 This study’s development of an AI-based dengue forecasting and monitoring sys-
226 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 227 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
228 and local health units in Iloilo City and Province stand to benefit greatly
229 from the system. With dengue predictions, we can help these agencies opti-
230 mize their response strategies and implement targeted prevention measures
231 in high-risk areas before cases escalate.
- 232 • **Local Government Units (LGUs):** LGUs can use the system to support
233 their disaster management and health initiatives by proactively addressing
234 dengue outbreaks. The predictive insights allow for more efficient planning
235 and resource deployment in barangays and communities most vulnerable to
236 outbreaks, improving overall public health outcomes.
- 237 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
238 occupancy rates during dengue season will benefit from early outbreak fore-
239 casts that can help in managing patient inflow and ensuring adequate hos-
240 pital capacity.
- 241 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
242 able insights for researchers studying infectious disease patterns and policy-
243 makers focused on strengthening the national AI Roadmap. The system’s
244 data can support broader initiatives for sustainable health infrastructure
245 and inform policy decisions on resource allocation for dengue control.
- 246 • **Community Members:** By reducing the frequency and severity of outbreaks,
247 this study ultimately benefits the community at large. This allows for timely

248 awareness campaigns and community engagement initiatives, empowering
249 residents with knowledge and preventative measures to protect themselves
250 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

274 public health concern. Studies suggest that outbreak thresholds should be context-
 275 specific, given the variability in transmission dynamics across different locations
 276 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
 277 Channel often base thresholds on 2 standard deviations (SD) above the mean
 278 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
 279 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
 280 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
 281 significantly across regions and time, making them inconsistent and incomparable.

282 From the studies above, this research implements an outbreak definition basing
 283 the threshold on 2 standard deviations (SD) above the mean number of historic
 284 dengue cases. It is important to note that for future outbreak definitions, addi-
 285 tional local context like available hospital space etc., must be taken into account
 286 for a more effective outbreak definition.

287 **2.3 Existing System: RabDash DC**

288 RabDash, developed by the University of the Philippines Mindanao, is a web-
 289 based dashboard for rabies data analytics. It combines predictive modeling with
 290 genomic data, enabling local health authorities to optimize interventions and al-
 291 locate resources more effectively. RabDash’s modules include trend visualization,
 292 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
 293 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

294 For DengueWatch, RabDash serves as a strong inspiration, particularly in
 295 its monitoring, historical trend visualization, and forecasting capabilities. These
 296 features align well with the needs of dengue control efforts, providing real-time
 297 insights into outbreak trends and enabling more effective, data-driven decision-
 298 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
 299 breaks similarly require time-series forecasting models. By using LSTM, RabDash
 300 effectively models trends in outbreak data, which provides a framework for adapt-
 301 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
 302 form traditional methods, such as ARIMA and MLP, in handling the complexities
 303 of time-dependent epidemiological data (Ligue & Ligue, 2022).

304 2.4 Deep Learning

305 The study of (Ligue & Ligue, 2022) highlights how data-driven models can help
306 predict dengue outbreaks. The authors compared traditional statistical meth-
307 ods, such as non-seasonal and seasonal autoregressive integrated moving average
308 (ARIMA), and traditional feed-forward network approach using a multilayer per-
309 ceptron (MLP) model with a deep learning approach using the long short-term
310 memory (LSTM) architecture in their prediction model. They found that the
311 LSTM model performs better in terms of accuracy. The LSTM model achieved a
312 much lower root mean square error (RMSE) compared to both MLP and ARIMA
313 models, proving its ability to capture complex patterns in time-series data (Ligue
314 & Ligue, 2022). This superior performance is attributed to LSTM’s capacity
315 to capture complex, time-dependent relationships within the data, such as those
316 between temperature, rainfall, humidity, and mosquito populations, all of which
317 contribute to dengue incidence (Ligue & Ligue, 2022).

318 2.5 Kalman Filter

319 The Kalman Filter is another powerful tool for time-series forecasting that can be
320 integrated into our analysis. It provides a recursive solution to estimating the state
321 of a linear dynamic system from a series of noisy measurements. Its application
322 in epidemiological modeling can enhance prediction accuracy by accounting for
323 uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters
324 are effective in predicting infectious disease outbreaks by refining estimates based
325 on observed data. A study published in *Frontiers in Physics* utilized the Kalman
326 filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman
327 filter effectively tracked the progression of deaths and cases, providing critical in-
328 sights for public health decision-making (Ahmadini et al., 2021). Another research
329 article in *PLOS ONE* focused on tracking the effective reproduction number (R_t)
330 of COVID-19 using a Kalman filter. This method estimated the growth rate of
331 new infections from noisy data, demonstrating that the Kalman filter could main-
332 tain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli,
333 Bullano, Kucinskas, & Rondón-Moreno, 2021).

334 Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM
335 models using our own collected dengue case data along with weather data to
336 identify the most effective model for real-time forecasting.

2.6 Weather Data

The relationship between weather patterns and mosquito-borne diseases is inherently nonlinear, meaning that fluctuations in disease cases do not respond proportionally to changes in climate variables (Colón-González, Fezzi, Lake, & Hunter, 2013). Weather data, such as minimum temperature and accumulated rainfall, are strongly linked to dengue case fluctuations, with effects observed after several weeks due to mosquito breeding and virus incubation cycles. Integrating these lagged weather effects into predictive models can improve early warning systems for dengue control (Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests that weather-based forecasting models using variables like mean temperature and cumulative rainfall can provide early warnings of dengue outbreaks with high sensitivity and specificity, enabling predictions up to 16 weeks in advance (Hii, Zhu, Ng, Ng, & Rocklöv, 2012).

We will utilize weather data, including variables such as temperature, rainfall, and humidity, as inputs for our dengue forecasting model. Given the strong, nonlinear relationship between climate patterns and dengue incidence, these weather variables, along with their lagged effects, are essential for enhancing prediction accuracy and providing timely early warnings for dengue outbreaks.

2.7 Chapter Summary

This chapter reviewed key literature relevant to our study, focusing on existing systems, predictive modeling techniques and the role of weather data in forecasting dengue outbreaks. We examined systems like RabDash DC, which integrates predictive modeling with real-time data to inform public health decisions, providing a foundational structure for our Dengue Watch System. Additionally, deep learning approaches, particularly Long Short-Term Memory (LSTM) networks, were highlighted for their effectiveness in time-series forecasting, while alternative methods such as ARIMA and Kalman Filters were considered for their ability to model complex temporal patterns and handle noisy data.

The literature further underscores the significance of weather variables—such as temperature and rainfall—in forecasting dengue cases. Studies demonstrate that these variables contribute to accurate outbreak prediction models. Leveraging these insights, our study will incorporate both weather data and historical dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

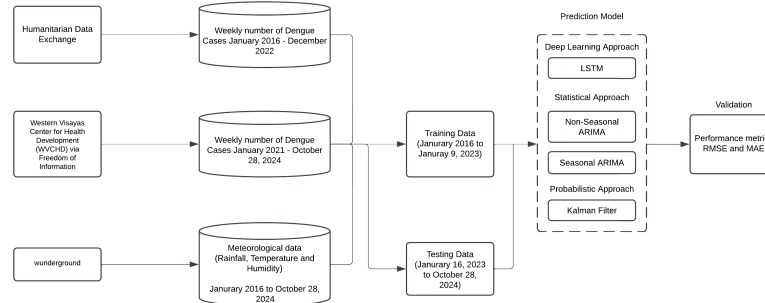

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

3.1 Research Activities

3.1.1 Gather Dengue Data and Climate Data to Create a Complete Dataset for Forecasting

Acquisition of Dengue Case Data

The historical dengue case dataset used in this study was obtained from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD) via Freedom of Information (FOI) requests. The decision to use weekly intervals was driven by the need for precision and timeliness in capturing fluctuations in dengue cases and weather conditions. Dengue transmission is influenced by short-term changes in weather variables such as rainfall and temperature, which impact mosquito breeding and virus transmission cycles. A weekly granularity allowed the model to better capture these short-term trends, enabling more accurate predictions and responsive public health interventions.

Moreover, using a weekly interval provided more data points for training the models compared to a monthly format. This is particularly critical in time series modeling, where larger datasets help improve the robustness of the model and its ability to generalize to new data. Also, the collection of weather data was done by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall, temperature, and humidity) from Weather Underground (wunderground.com).

Data Fields

- **Time.** Represents the specific year and week corresponding to each entry in the dataset.
- **Rainfall.** Denotes the observed average rainfall, measured in millimeters, for a specific week.
- **Humidity.** Refers to the observed average relative humidity, expressed as a percentage, for a specific week.
- **Max Temperature.** Represents the observed maximum temperature, measured in degrees Celsius, for a specific week.
- **Average Temperature.** Represents the observed average temperature, measured in degrees Celsius, for a specific week.

- 413 • **Min Temperature.** Represents the observed minimum temperature, mea-
414 sured in degrees Celsius, for a specific week.
- 415 • **Wind.** Represents the observed wind speed, measured in miles per hour
416 (mph), for a specific week.
- 417 • **Cases.** Refers to the number of reported dengue cases during a specific
418 week.

419 **Data Integration and Preprocessing**

420 The dengue case data was integrated with the weather data to create a com-
421 prehensive dataset, aligning the data based on corresponding timeframes. The
422 dataset underwent a cleaning process to address any missing values, outliers, and
423 inconsistencies to ensure its accuracy and reliability. To ensure that all features
424 and the target variable were on the same scale, a MinMaxScaler was applied to
425 normalize both the input features (climate data) and the target variable (dengue
426 cases).

427 **Exploratory Data Analysis (EDA)**

- 428 • Analyzed trends, seasonality, and correlations between dengue cases and
429 weather factors.
- 430 • Created visualizations like time series plots and scatterplots to highlight
431 relationships and patterns in the data.

432 **Outbreak Detection**

433 To detect outbreaks, we computed the outbreak threshold value of dengue cases
434 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

435 where μ is the historical mean and σ is the standard deviation.

436 3.1.2 Develop and Evaluate Deep Learning Models for 437 Dengue Case Forecasting

438 The deep learning models were developed and trained to forecast weekly dengue
439 cases using historical weather data (rainfall, temperature, wind, and humidity)
440 and dengue case counts. The dataset was normalized and divided into training and
441 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
442 for preparing and training the model are outlined below.

443 Data Preprocessing

444 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
445 ture, wind, humidity) and dengue case counts. The "Time" column was converted
446 to a datetime format to ensure proper temporal indexing. To standardize the data
447 for training, MinMaxScaler was employed, normalizing the feature values and tar-
448 get variable to a range of 0 to 1. This step ensured that the models could efficiently
449 process the data without being biased by feature scaling differences.

450 LSTM Model

451 To prepare the data for LSTM, a sliding window approach was utilized. Sequences
452 of weeks of normalized features were constructed as input, while the dengue case
453 count for the subsequent week was set as the target variable. This approach en-
454 sured that the model leveraged temporal dependencies in the data for forecasting.

455 The LSTM model architecture consisted of an input layer, a single LSTM layer
456 with 64 units and ReLU activation, followed by a dense layer with a single output
457 neuron to predict the dengue case count. Key hyperparameters included:

- 458 • Window Size: 5, 10, and 20 weeks, representing the time steps used in the
459 sequence data for each prediction.
- 460 • Epochs: 100 epochs were used for training, balancing sufficient training
461 time with computational efficiency also implementing early stopping to avoid
462 overfitting.
- 463 • Batch Size: 1, allowing the model to process one sequence at a time, which
464 is beneficial for small datasets but increases training time.

465 • **Optimizer:** The Adam optimizer was chosen for its adaptive learning capa-
466 bilities and stability in training. A custom learning rate of 0.001 was set to
467 ensure gradual convergence and minimize risk of overfitting.

468 The dataset was split into training and test sets to evaluate the model’s per-
469 formance and generalizability:

470 • **Training Set:** 80% of the data (572 sequences) was used for model training,
471 enabling the LSTM to learn underlying patterns in historical dengue case
472 trends and their relationship with weather variables.

473 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
474 testing

475 After training, predictions on both the training and test datasets were rescaled
476 to their original scale using the inverse transformation of MinMaxScaler. Model
477 performance was evaluated using the mean squared error (MSE), root mean
478 squared error (RMSE) and mean absolute error (MAE).

479 **Hyperparameter Tuning**

480 After identifying the optimal window size, it is saved and used to generate the
481 final data sequences, which are then utilized during hyper-parameter tuning.

482 To enhance the performance of the LSTM model in predicting dengue cases,
483 Bayesian Optimization was employed using the Keras Tuner library. The tuning
484 process aimed to minimize the validation loss (mean squared error) by adjusting
485 key model hyper-parameters. The search space is summarized below:

486 **LSTM units:**

- 487 • min value: 32
- 488 • max value: 256
- 489 • step: 32
- 490 • sampling: linear

491 **Learning Rate:**

492 • min value: 0.0001

493 • max value: 0.01

494 • step: None

495 • sampling: log

496 The tuner was instantiated with:

497 • **max trials = 20:** Limiting the search to 20 different configurations

498 • **executions per trial = 3:** Running each configuration thrice to reduce
499 variance

500 • **validation split = 0.2:** Reserving 20% of the training data for validation

501 ARIMA

502 The ARIMA model was employed to forecast weekly dengue cases using historical
503 weather data (rainfall, max temperature, and humidity) as exogenous variables
504 and historical case counts as the primary dependent variable. The dataset was
505 split into training (80%) and testing (20%) sets. To determine the optimal con-
506 figuration for the ARIMA model, a grid search was conducted over the following
507 parameter ranges:

508 • p (autoregressive order): 0 to 3

509 • d (differencing order): 0 to 2

510 • q (moving average order): 0 to 3

511 The combinations of these parameters were evaluated by fitting an ARIMA model
512 for each set of (p, d, q) values. The model's performance was assessed using the
513 mean squared error (MSE) between the predicted and actual dengue cases in the
514 test set. The combination yielding the lowest MSE was selected as the optimal
515 parameter configuration.

516 The fitted ARIMA model was used to forecast weekly dengue cases for the
517 test dataset. Predictions were directly assigned to the PredictedCases column in
518 the test dataset.

519 Steps to Create the ARIMA Model:

- 520 1. **Data Preprocessing:** Prepare the dataset by handling any missing values
521 and scaling the data if necessary to improve model convergence and stability.
- 522 2. **Hyperparameter Tuning:** Use a grid search on potential ARIMA param-
523 eters (p, d, q) to identify the configuration that minimizes error. The optimal
524 parameters were found to be **(1, 2, 2)**.
- 525 3. **Model Training:**
 - 526 • Set the number of iterations to 400 to ensure thorough training and
527 convergence.
 - 528 • Train the ARIMA model on 80% of the data and reserve 20% for test-
529 ing.

530 Seasonal ARIMA (SARIMA)

- 531 1. **Data Preprocessing**
 - 532 • Handle missing values through interpolation or imputation.
 - 533 • Normalize or standardize features to ensure stable training.
 - 534 • Split data into training (80%) and testing (20%) sets while maintaining
535 temporal continuity.
- 536 2. **Seasonality Analysis**
 - 537 • Perform time series decomposition to examine trend, seasonality, and
538 residual components.
 - 539 • Identify seasonality using autocorrelation plots and spectral analysis.
 - 540 • A periodicity of **52 weeks** was detected, justifying the use of a seasonal
541 model.
- 542 3. **Hyperparameter Tuning**
 - 543 • Conduct a grid search to optimize SARIMA parameters $(p, d, q)(P, D, Q)[S]$.
 - 544 • Determine optimal configuration for seasonal and non-seasonal compo-
545 nents.
 - 546 • Verify stationarity through Augmented Dickey-Fuller (ADF) test.
- 547 4. **Model Training**

- 548 • Fit the SARIMA model on the training dataset, incorporating exoge-
549 nous variables such as rainfall, temperature, and humidity.
- 550 • Set a maximum number of iterations to ensure convergence.
- 551 • Monitor model diagnostics (residual analysis) to confirm the absence
552 of autocorrelation in residuals.

553 5. Forecasting and Validation

- 554 • Generate out-of-sample forecasts for future dengue cases.
- 555 • Compare predicted values against actual data to assess real-world ap-
556 plicability.
- 557 • Visualize results with line plots and confidence intervals.

558 Kalman Filter:

- 559 • Input Variables: The target variable (Cases) was modeled using three re-
560 gressors: rainfall, max temperature, and humidity.
- 561 • Training and Testing Split: The dataset was split into 80% training and
562 20% testing to evaluate model performance.
- 563 • Observation Matrix: The Kalman Filter requires an observation matrix,
564 which was constructed by adding an intercept (column of ones) to the re-
565 gressors.

566 The Kalman Filter’s EM method was employed for training, iteratively esti-
567 mating model parameters over 10 iterations. The smooth method was used to
568 compute the smoothed state estimates for the training data. Observation matri-
569 ces for the test data were constructed similarly, ensuring compatibility with the
570 trained model.

571 Kalman Filter Methodology with Matrix Calculations

572 **Measurement Acquisition:** Obtain the measurement: (z_k) of the system’s state
573 with associated confidence. This measurement matrix provides a noisy observation
574 of the true state.

575 The dataset was split into training and test sets to evaluate the Kalman Filter’s
576 performance and generalizability:

577 • **Training Set:** 80% of the data was used for training, enabling the Kalman
578 Filter model to capture key patterns.

579 • **Test Set:** The remaining 20% of the data was reserved for testing.

580 **Prediction Step:**

581 • Predict the next state:

$$\hat{x}_{k|k-1} = A\hat{x}_{k-1|k-1} + Bu_k$$

582 • Update the state covariance:

$$P_{k|k-1} = AP_{k-1|k-1}A^T + Q$$

583 where Q is the process noise covariance matrix.

584 **Compute Residual:** Calculate the residual:

$$y_k = z_k - H\hat{x}_{k|k-1}$$

585 where H is the observation matrix. This residual represents the new information
586 from the measurement.

587 **Scaling Factor (Kalman Gain):**

588 • Compute the Kalman Gain:

$$K_k = P_{k|k-1}H^T (HP_{k|k-1}H^T + R)^{-1}$$

589 where R is the measurement noise covariance matrix.

590 • The Kalman Gain determines the weight of the measurement relative to the
591 prediction.

592 **State Update:**

593 • Update the state estimate:

$$\hat{x}_{k|k} = \hat{x}_{k|k-1} + K_k y_k$$

594 blending the prediction and measurement.

595 **Uncertainty Update:**

596 • Update the state covariance:

$$P_{k|k} = (I - K_k H)P_{k|k-1}$$

597 where I is the identity matrix.

598 **3.1.3 Integrate the Predictive Model into a Web-Based** 599 **Data Analytics Dashboard**

600 **Dashboard Design and Development**

- 601 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 602 – Interactive visualizations of yearly dengue case trends.
 - 603 – Data input and update forms for dengue and weather data.
 - 604 – Map display of dengue cases in each district in Iloilo City

605 **Model Integration and Deployment**

- 606 • Deploy the best-performing model within the dashboard as a backend service
607 to enable real-time or periodic forecasting.

608 **3.1.4 System Development Framework**

609 The Agile Model is the birthchild of both iterative and incremental approaches
610 in Software Engineering. It aims to be flexible and effective at the same time by
611 being adaptable to change. It's also important to note that small teams looking
612 to construct and develop projects quickly can benefit from this kind of method-
613 ology. As the Agile Method focuses on continuous testing, quality assurance is a
614 guarantee since bugs and errors are quickly identified and patched.

615 **3.1.5 Design, Building, Testing, and Integration**

616 **Design and Development**

617 After brainstorming and researching the most appropriate type of application to
618 accommodate both the prospected users and the proposed solutions, the team has
619 decided to proceed with a web application. Given the time constraints and avail-
620 able resources, we believe this is the most pragmatic and practical move. The next
621 step is to select modern and stable frameworks that align with the fundamental
622 ideas we have learned at the university. The template obtained from WVCHD
623 and Iloilo Provincial Epidemiology and Surveillance Unit was meticulously ana-
624 lyzed to create use cases and develop a preliminary well-structured database that

625 adheres to the requirements needed to produce a quality application. The said use
626 cases serve as the basis of general features. Part by part, these are converted into
627 code, and with the help of selected libraries and packages, it resulted in the de-
628 sired outcome that may still modified and extended since it is continuously being
629 developed.

630 **Testing and Integration**

631 Each feature will be rigorously user-tested to ensure quality assurance, with par-
632 ticular emphasis on prerequisite features, as development cannot progress properly
633 if these fail. Moreover, integration between each feature serves as a pillar for a
634 cohesive user experience. Presently, we have not been able to use performance
635 metrics to measure the system’s performance, as developing and connecting the
636 core features is the utmost priority.

637 **3.2 Development Tools**

638 **3.2.1 Software**

639 **Github**

640 GitHub is a cloud-based platform that tracks file changes using Git, an open-
641 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
642 used in the project to store the application’s source code, manage the system’s
643 source version control, and serve as a repository for the Latex files used in the
644 actual research.

645 **Visual Studio Code**

646 Visual Studio Code is a free, lightweight, and cross-platform source code editor
647 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
648 this project’s programming and scripting languages, it was chosen as the primary
649 source code editor.

650 Django

651 Django is a free and open-sourced Python-based web framework that offers an
652 abstraction to develop and maintain a secure web application. As this research
653 aims to create a well-developed and maintainable application, it is in the best
654 interest to follow an architectural pattern that developers and contributors in the
655 future can understand. Since Django adheres to Model-View-Template (MVT)
656 that promotes a clean codebase by separating data models, business logic, and
657 presentation layers, it became the primary candidate for the application's back-
658 bone.

659 Next.js

660 A report by Statista (2024) claims that React is the most popular front-end frame-
661 work among web developers. However, React has limitations that can be a nui-
662 sance in rapid software development, which includes routing and performance op-
663 timizations. This is where Next.js comes in—a framework built on top of React.
664 It offers solutions for React's deficiency, making it a rising star in the framework
665 race.

666 Postman

667 As the application heavily relies on the Application Programming Interface (API)
668 being thrown by the backend, it is a must to use a development tool that facilitates
669 the development and testing of the API. Postman is a freemium API platform
670 that offers a user-friendly interface to create and manage API requests (*What is*
671 *Postman? Postman API Platform*, n.d.).

672 3.2.2 Hardware

673 The web application is continuously being developed on laptop computers with
674 minimum specifications of an 11th-generation Intel i5 CPU and 16 gigabytes of
675 RAM.

676 3.2.3 Packages

677 Django REST Framework

678 Django Rest Framework (DRF) is a third-party package for Django that provides a
679 comprehensive suite of features to simplify the development of robust and scalable
680 Web APIs (Christie, n.d.). These services include Serialization, Authentication
681 and Permissions, Viewsets and Routers, and a browsable API .

682 Leaflet

683 One of the features of the web application is the ability to map the number
684 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
685 most importantly, stable JavaScript package that can do the job. With its ultra-
686 lightweight size, it offers a comprehensive set of features that does not trade
687 off performance and usability (*Leaflet — an open-source JavaScript library for*
688 *interactive maps*, n.d.).

689 Chart.js

690 Another feature of the application is to provide users with informative, approach-
691 able data storytelling that is easy for everyone to understand. The transformation
692 of pure data points and statistics into figures such as charts is a big factor. Thus,
693 there is a need for a package that can handle this feature without compromising
694 the performance of the application. Chart.js is a free and open-source JavaScript
695 package that is made to meet this criteria as it supports various types of charts
696 (*Chart.js*, n.d.).

697 Tailwind CSS

698 Using plain CSS in production-quality applications can be counterproductive.
699 Therefore, CSS frameworks were developed to promote consistency and accelerate
700 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
701 which offers low-level utility classes that can be applied directly to each HTML
702 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
703 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
704 project, using this framework is a wise choice due to its stability and popularity
705 among developers.

706 **Shadcn**

707 Shadcn offers a collection of open-source UI boilerplate components that can be
708 directly copied and pasted into one's project. With the flexibility of the provided
709 components, Shadcn allows developers to have full control over customization and
710 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
711 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

712 **Zod**

713 Data validation is integral in this web application since it will handle crucial data
714 that will be used for analytical inferences and observations. Since Zod is primarily
715 used for validating and parsing data, it ensures proper communication between
716 the client and the server (Zod, n.d.).

3.3 Calendar of Activities

A Gantt chart showing the schedule of the activities is included below. Each bullet represents approximately one week of activity.

Table 3.1: Timetable of Activities for 2024

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. Dengue Case Data: The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. Weather Data: Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

```
data.head()
```

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases
0	2011-01-03	9.938571	29.444400	25.888890	23.888900	11.39	86.242857	5

738 4.2 Exploratory Data Analysis

739 From the summary above, the dataset consists of 720 weekly records with 8
740 columns:

- 741 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 742 • **Rainfall.** Weekly average rainfall (mm)
- 743 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
744 temperature data (C)
- 745 • **Wind.** Wind speed (m/s)
- 746 • **Humidity.** Weekly average humidity (%)
- 747 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases
count	720	720.000000	720.000000	720.000000	720.000000	720.000000	720.000000	720.000000

std	NaN	35.448846	2.616379	0.999800	1.291659	2.446703	2.831674	37.144813

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks. To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

760 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 761 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

762

763 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 764 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 765 dengue cases. Notably, peak cases are observed during certain periods approx-
 766 imately 3 years, potentially aligning with specific climatic conditions such as
 767 increased rainfall or temperature changes. This underscores the importance of
 768 incorporating climate variables into the forecasting model.

769 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 770 and selected features, including rainfall, humidity, maximum temperature, aver-
 771 age temperature, minimum temperature, and wind speed. Among these, rainfall
 772 exhibits the highest positive correlation with dengue cases (correlation coefficient
 773 0.13), indicating that increased rainfall may contribute to higher cases counts.
 774 This aligns with existing studies suggesting that stagnant water from heavy rain-
 775 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 776 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 777 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 778 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 779 relationship than average and minimum temperature.

780 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 781 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

4.3 Outbreak Detection

To identify outbreaks, we calculated the outbreak threshold value using the historical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

where μ is the historical mean and σ is the standard deviation.

This result indicates that dengue cases exceeding 98 in Iloilo City can be considered an outbreak. However, it is important to note that this threshold serves only as a baseline. Additional parameters, such as the number of hospital beds available in the city, must be considered to compute a more effective threshold and develop an appropriate response strategy.

796 4.4 Model Training Results

797 The models were evaluated using three metrics: MSE, RMSE, and MAE. The
798 table below provides a summary and comparative analysis of each model's results
799 across these metrics, offering insights into the strengths and limitations of each
800 forecasting technique for dengue case prediction in Iloilo City. The lower values
801 of the three metrics indicate better forecasting performance. Table 4.1 shows that
802 the models performed differently on testing data. LSTM outperformed the other
803 models with the lowest RMSE, MSE, and MAE while the other three models had
804 relatively higher values for the three metrics.

Method	LSTM (Window Size 10)	Seasonal ARIMA (2, 0, 2)(0, 1, 1)	ARIMA (1, 2, 2)	Kalman Filter
Testing MSE	260.93	1109.69	1521.48	1474.82
Testing RMSE	16.15	33.31	39.00	38.40
Testing MAE	9.30	18.08	25.80	22.33

Table 4.1: Comparison of Models

805 4.4.1 LSTM Model

806 Figure 4.9 illustrate the performance of the model in predicting dengue cases for
807 each of the specified window sizes. The plots demonstrate that the predicted
808 cases closely follow the trend of the actual cases, indicating that the LSTM model
809 successfully captured the underlying patterns in the data. Despite the fact that the
810 test data is unseen, the model shows a remarkable ability to generalize, suggesting
811 that the model is effectively leveraging past observations to predict future trends.

Figure 4.9: Comparison of Window Sizes

Further evaluating which window size is most suitable for the prediction model, Table 4.2 shows the evaluation metrics for each window size used in the LSTM model training.

Window Size	MSE	RMSE	MAE	R^2
5	274.70	16.57	9.57	0.84
10	260.93	16.15	9.30	0.85
20	297.11	17.24	9.84	0.83

Table 4.2: Comparison of Window Sizes

The results indicate that a window size of 10 weeks provides the most accurate predictions, as evidenced by the lowest MSE (260.93) and RMSE (16.15) values. Although the 10-week window size yields the lowest MAE (9.30), the 5-week window follows closely with 9.57, while the 20-week window is slightly higher at 9.84. These differences are relatively small, especially between the 5- and 10-week windows, indicating that the average prediction error remains fairly consistent across different window sizes.

Furthermore, the R^2 score of 0.85 for the 10-week window indicates that 85%

823 of the variability in the target variable (cases) is explained by the independent
824 variables (the inputs) in the model, making it a reliable configuration overall.
825 In contrast, the 5-week and 20-week windows yield R^2 scores of 0.84 and 0.83,
826 respectively, reflecting marginally lower explanatory power.

827 This suggests that using a 10-week sequence length effectively balances the
828 model’s ability to capture temporal dependencies with predictive accuracy, with-
829 out unnecessarily increasing model complexity or introducing additional noise
830 from longer sequences.

831 Using the 10-week sequence length identified as the optimal window size in
832 preliminary experiments, the dataset was reshaped accordingly and served as the
833 input for hyperparameter tuning. Although the tuning process successfully iden-
834 tified a configuration that minimized the validation loss during training, it did
835 not result in improved performance on the test set. In fact, the model’s evalua-
836 tion metrics slightly declined when compared to the baseline model trained with
837 manually selected hyperparameters.

Model	MSE	RMSE	MAE	R^2
Before tuning	260.93	16.15	9.30	0.85
After tuning	317.70	17.82	10.42	0.81

Table 4.3: Comparison of Model Performance Before and After Tuning (Using window size = 10)

838 This outcome suggests that the tuned model may have overfitted the validation
839 split, a common occurrence when working with relatively small datasets. It is also
840 possible that the default or manually chosen configuration was already close to
841 optimal in terms of generalization. Furthermore, although the tuning search space
842 was reasonably defined, it may have excluded other more effective hyperparameter
843 combinations. These results emphasize the importance of critically evaluating
844 tuning results and underscore that automated hyperparameter optimization does
845 not always guarantee better model performance on unseen data.

846 4.4.2 ARIMA Model

Figure 4.10: ARIMA Prediction Results for Test Set

847 The ARIMA model was developed to capture non-seasonal trends in the data.
 848 To determine the best model configuration, grid search was used to explore vari-
 849 ous combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**.
 850 The model was iteratively refined over **400 iterations** to ensure convergence to
 851 an optimal solution. Figure 4.10 illustrates the comparison between actual and
 852 predicted dengue cases in the test set. As shown in the plot, the ARIMA model
 853 struggled to capture the non-linear characteristics and abrupt spikes in the data.
 854 Consequently, it failed to accurately reflect the fluctuations and outbreak patterns
 855 seen in the actual case counts.

856 The model's performance was assessed using regression metrics to evaluate its
 857 forecasting capability. The ARIMA model yielded the following error metrics:

- 858 • **MSE (Mean Squared Error):** 1521.48
- 859 • **RMSE (Root Mean Squared Error):** 39.01
- 860 • **MAE (Mean Absolute Error):** 25.80

4.4.3 Seasonal ARIMA (SARIMA) Model

To address the limitations of the ARIMA model, a Seasonal ARIMA (SARIMA) model was developed to capture both non-seasonal and seasonal variations in the data.

Figure 4.11: Seasonal ARIMA Prediction Results for Test Set

This model incorporates seasonal parameters, which were tuned using grid search to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA, **400 iterations** were applied to ensure a robust fit. As shown in Figure 4.11, the SARIMA model demonstrates a notable improvement in performance. Unlike its non-seasonal counterpart, it effectively captures the general trend and aligns more closely with the peaks observed in the actual dengue cases, indicating its ability to model seasonal dynamics.

The model's performance was assessed using regression metrics to evaluate its forecasting capability. The SARIMA model yielded the following error metrics:

- **MSE:** 1109.69
- **RMSE:** 33.31

876

- MAE: 18.09

877

878

879

880

The lower error values, when compared to the ARIMA model, highlight the SARIMA model's superior capability in forecasting dengue cases. Its effectiveness in capturing seasonal patterns contributed to a more accurate representation of the actual cases.

881

4.4.4 Kalman Filter Model

Figure 4.12: Kalman Filter Prediction Results for Test Set

882

883

884

885

886

887

888

889

Figure 4.12 shows the comparison between the actual dengue cases and the predicted values on the test set. As illustrated in the plot, the Kalman Filter model demonstrates a moderate ability to follow the general trend of the actual data. While it effectively captures some rising and falling patterns, it still struggles to accurately replicate the sharp peaks and extreme values found in the real case counts. This limitation is particularly noticeable during the large spikes in 2022 and 2024.

890 The model's performance was evaluated using standard regression metrics.
891 The results are as follows:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

892 These metrics indicate that the Kalman Filter outperforms the ARIMA model
893 in terms of mean absolute error (MAE), suggesting better accuracy in captur-
894 ing day-to-day fluctuations. However, it still underperforms compared to the
895 SARIMA model, particularly in modeling seasonal trends and sharp outbreaks.
896 Despite its limitations, the Kalman Filter shows promise for short-term forecasting
897 due to its adaptability and real-time updating capability.

4.5 Preliminary System Requirements

4.5.1 Backend Requirements

Database Structure Design

Determining how data flows and how it would be structured is crucial in creating the system as it defines how extendible and flexible it would be for future features and updates. Thus, creating a comprehensive map of data ensures proper normalization that eliminates data redundancy and improves data integrity. Figure 4.13 depicts the designed database schema that showcases the relationship between the application's entities.

Figure 4.13: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

907 4.5.2 User Interface Requirements

908 Admin Interface

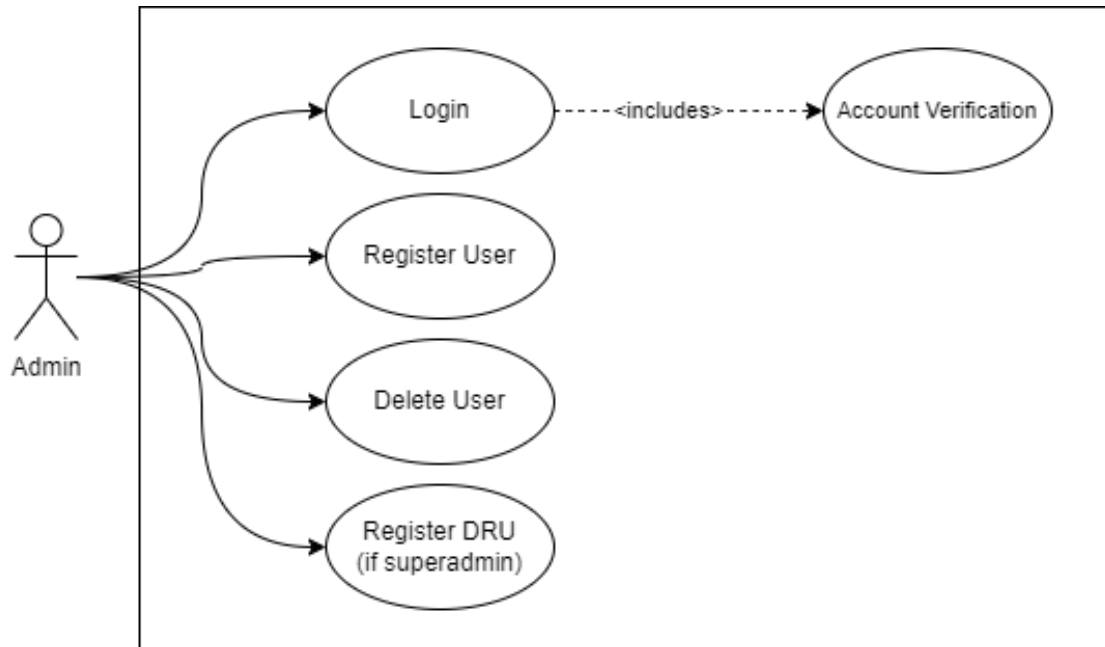

Figure 4.14: Use Case Diagram for Admin

909 Figure 4.14 shows the possible tasks that the admin can do in the application. To
910 protect the integrity of data, only the admins can register and delete accounts.
911 Both account creation and deletion will be done within the application.

Figure 4.15: Use Case Diagram for Encoder

913 Figure 4.15, on the other hand, illustrates the use cases for the system's primary
914 users. Since only the admin accounts can register a user, the registration process
915 is not part of it. Instead, the main features, which include reporting and viewing
916 records, are the only permitted actions for this type of user. The said processes
917 can be done in the application by filling out a form with details required for each
918 dengue case. As data is entered, it will be consolidated for model training and
919 used for further forecasting of dengue cases.

920 4.5.3 Security and Validation Requirements

921 Password Encryption

922 Storing passwords as plain text in the database is a disgrace and a mortal sin in
923 production. It is important to implement precautionary methods such as hashing
924 and salting, followed by encryption with a strong algorithm, to prevent bad actors
925 from using the accounts for malicious transactions. By default, Django generates
926 a unique random salt for each password and encrypts it with Password-Based Key
927 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
928 techniques ensures that in the event of a data breach, cracking these passwords
929 would be time-consuming and useless for the attackers.

930 Authentication

931 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
932 the mechanism operates in a stateless manner, tokens are served only after a
933 successful login, eliminating the need for the server to keep a record of the token,
934 which is vulnerable to session hijacking. In addition, these tokens are signed with
935 a secret key, ensuring they have not been tampered with.

936 Data Validation

937 Both the backend and frontend should validate the input from the user to preserve
938 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
939 from the user. By doing this, the user can only send proper requests to the server
940 which streamlines the total workflow. On the other hand, Django has also a built-
941 in validator that checks the data type and ensures that the input matches the
942 expected format on the server side. These validation processes ensure that only
943 valid and properly formatted data is accepted, which reduces the risk of errors
944 and ensures consistency across the web application.

945 4.5.4 Testing Process

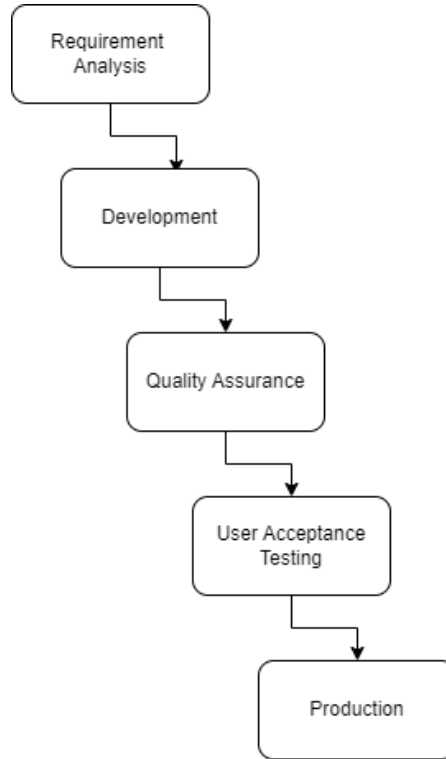

Figure 4.16: Testing Process for DengueWatch

946 As the system requirements and functionalities have been mentioned above, it
947 is important to implement testing to validate the system's performance and effi-
948 cacy. Since dengue reports include confidential information, anonymized historical
949 dengue reports were used to train the model and create the foundational architec-
950 ture of the system. By using functional tests, data validation and visualization can
951 be ensured for further continual improvements. Security testing is also important
952 as it is needed to safeguard confidential information when the system is deployed.
953 It includes proper authentication, permission views, and mitigating common in-
954 jection attacks. Finally, a user acceptance test from the prospected users, in this
955 case, the Iloilo City Epidemiology and Surveillance Unit, is crucial to assess its
956 performance and user experience. It enables the developers to confirm if the sys-
957 tem meets the needs of the problem, and once confirmed, it will be deployed and
958 further evaluated to ensure stability and reliability in live operation.

4.6 System Prototype

4.6.1 Guest Interface

The Guest Interface is intended for all visitors of the web application. It shows the related statistics for dengue cases in a particular area and time. As the system is still in its testing phase, the data converted into charts shown in Figure 4.17 are generated from Python's Faker library.

Figure 4.17: Dashboard for Guests

965 4.6.2 Personnel Interface

966 User Authentication, and Login

967 To protect the data's integrity in production, it has been decided that the registration process will not be visible. Instead, an admin must register a user using
968 a different interface. As of the moment, registering a user is done using API via
969 Postman. In the login process, the system implements HTTP-only cookies that
970 contains the JSON Web Tokens (JWT) to protect against XSS attacks. After
971 proper credentials have been provided, it will redirect to the user's home page.
972

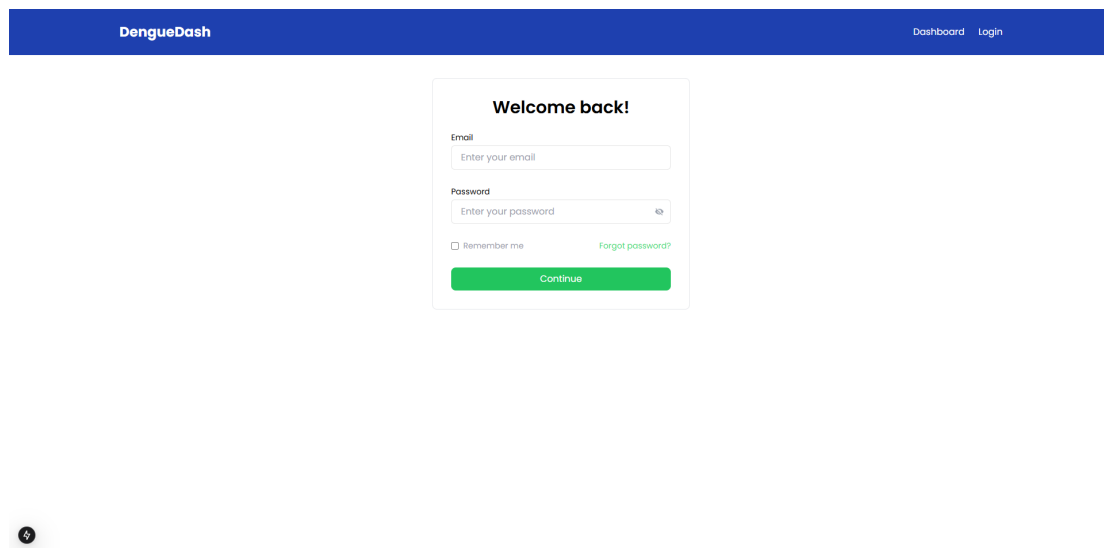

Figure 4.18: Login Page for Users

973 Encoder's View

974 Figures 4.19 and 4.20 show the digitized counterpart of the form obtained from the
975 Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to support
976 expandability for future features, some fields were modified to accommodate
977 more detailed input. It is worth noting that all of the included fields adhere to the
978 latest Philippine Integrated Disease and Surveillance Response (PIDSR) Dengue
979 Forms, which the referenced form was based on. By doing this, it is assumed
980 that the targeted users will have a familiarity when deployed on a national scale.
981 On a further note, the case form includes the patient's basic information, dengue
982 vaccination status, consultation details, laboratory results, and the outcome.

Figure 4.20: Second Part of Case Report Form

983 Once the data generated from the case report form is validated, it will be
 984 assigned as a new case and can be accessed through the Dengue Reports page, as
 985 shown in Figure 4.21. The said page displays basic information about the patient
 986 related to a specific case, including their name, address, date of consultation, and
 987 clinical and case classifications. It is also worth noting that it only shows cases
 988 the user is permitted to view. For example, in a local Disease Reporting Unit
 989 (DRU) setting, the user can only access records that came from the same DRU.
 990 On the other hand, in a consolidated surveillance unit such as a regional and
 991 provincial quarter, its users can view all the records that came from all the DRUs
 992 that report to them. Moving forward, Figure 4.22 shows the detailed case report
 993 of the patient on a particular consultation date.

The screenshot shows the DengueDash application interface. On the left is a sidebar menu with the following items: Analytics, Forms, Data Tables (expanded), Dengue Reports, Another Report, and Settings. The main content area is titled 'Building Your Application > Data Fetching' and displays a table of dengue reports. The table has columns for Case ID, Name, Barangay, City, Date Consulted, Clinical Classification, Case Classification, and Action. There are 12 rows of data, each with an 'Open' button in the Action column. At the bottom of the table, there is a pagination control showing '1' of 218 items.

Case ID	Name	Barangay	City	Date Consulted	Clinical Classification	Case Classification	Action
