Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This research focused on developing a centralized system for monitoring and forecasting dengue trends in Iloilo City, incorporating graphical visualizations such as heatmaps, trends, and historical graphs. The study explored the application of artificial intelligence (AI) in dengue prediction, utilizing deep learning models. The performance of the Long Short-Term Memory (LSTM) model was compared with traditional statistical methods, including non-seasonal and seasonal Autoregressive Integrated Moving Average (ARIMA) models and the Kalman Filter. Evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) were used to identify the most effective model for integration into the system. Forecasting was based on climate variables such as temperature, rainfall, relative humidity, and previous monthly case counts. The LSTM model emerged as the best performer with an RMSE of 16.15, demonstrating its suitability for time-series predictions, while the Kalman Filter showed the poorest performance with an RMSE of 38.40. By integrating predictive analytics with real-time data visualization, the proposed system aims to support public health agencies, such as the Department of Health (DOH), by providing actionable insights for proactive intervention strategies. This AI-driven solution enhances traditional outbreak reporting systems by enabling timely, data-informed decisions to mitigate the impact of dengue in the region.

Keywords: ARIMA, artificial intelligence, dengue prediction, LSTM, Kalman Filter, deep learning, climate variables, public health, outbreak mitigation

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

157 This study explores the monitoring and forecasting of dengue outbreaks by an-
158 alyzing key factors such as temperature, relative humidity, and historical dengue
159 cases, using different models. The findings aim to provide an advanced, AI-driven
160 alternative for dengue prevention and control, targeting agencies like the Depart-
161 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
162 in Iloilo City, this research aspires to improve outbreak responses through cutting-
163 edge technology rather than traditional reporting methods.

164 1.2 Problem Statement

165 Dengue remains a critical public health challenge worldwide, with cases increasing
166 due to the easing of COVID-19 restrictions and heightened global mobility. While
167 a temporary decline in cases was observed during the pandemic (2020–2022) due
168 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
169 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
170 regions like the Philippines, the threat is particularly severe. In Iloilo City and
171 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
172 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
173 pital beds occupied by dengue patients, highlighting the urgent need for effective
174 predictive tools. The lack of a reliable system to monitor and forecast dengue
175 outbreaks contributes to delayed interventions, exacerbating public health risks
176 and healthcare burdens in the region.

177 1.3 Research Objectives

178 1.3.1 General Objective

179 This study aims to develop an AI-based dengue forecasting and monitoring system
180 for Iloilo City and Province. The researchers will train and compare multiple deep
181 learning models to predict dengue case trends based on climate data and historical
182 dengue cases to help public health officials in possible dengue case outbreaks.

183 1.3.2 Specific Objectives

184 Specifically, this study aims to:

- 185 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
186 (including temperature, rainfall, wind, and humidity) from online sources.
187 Combine and aggregate these data into a unified dataset to facilitate com-
188 prehensive dengue case forecasting.
- 189 2. Evaluate deep learning models for predicting dengue cases using metrics
190 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
191 and Mean Squared Error (MSE). Compare the performance of these models
192 to determine the most accurate forecasting approach.
- 193 3. Develop a web-based analytics dashboard that integrates a predictive model
194 and provides data management system for dengue cases in Iloilo City and
195 the Province.
- 196 4. Assess the usability and effectiveness of the analytics dashboard through
197 structured feedback and surveys involving health professionals and policy-
198 makers.

199 1.4 Scope and Limitations of the Research

200 This study aims to gather dengue data from the Iloilo Provincial Health Office
201 and climate data from online sources such as PAGASA or weatherandclimate.com.
202 These data will be preprocessed, cleaned, and combined into a unified dataset to
203 facilitate comprehensive dengue case forecasting. However, the study is limited by
204 the availability and completeness of historical data. Inconsistent or missing data
205 points may introduce biases and reduce the quality of predictions. Furthermore,
206 the granularity of the data will be in a weekly format.

207 To evaluate deep learning models for predicting dengue cases, the study will
208 train and compare the performance of various models, using metrics like Mean
209 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
210 aim to provide accurate forecasts, their performance is heavily influenced by the
211 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
212 predictions. Additionally, the models cannot fully account for external factors
213 such as public health interventions or socio-economic conditions which may impact
214 dengue transmission dynamics.

215 The study also involves developing a web-based analytics dashboard that in-
216 tegrates predictive models and provides a data management system for dengue
217 cases in Iloilo City and the Province. This dashboard will offer public health
218 officials an interactive interface to visualize dengue trends, input new data, and

219 identify risk areas. However, its usability depends on feedback from stakeholders,
220 which may vary based on their familiarity with analytics tools. Moreover, exter-
221 nal factors such as limited internet connectivity or device availability in remote
222 areas may affect the system’s adoption and effectiveness. While the dashboard
223 provides valuable insights, it cannot incorporate all factors influencing dengue
224 transmission, emphasizing the need for ongoing validation and refinement.

225 1.5 Significance of the Research

226 This study’s development of an AI-based dengue forecasting and monitoring sys-
227 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 228 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
229 and local health units in Iloilo City and Province stand to benefit greatly
230 from the system. With dengue predictions, we can help these agencies opti-
231 mize their response strategies and implement targeted prevention measures
232 in high-risk areas before cases escalate.
- 233 • **Local Government Units (LGUs):** LGUs can use the system to support
234 their disaster management and health initiatives by proactively addressing
235 dengue outbreaks. The predictive insights allow for more efficient planning
236 and resource deployment in barangays and communities most vulnerable to
237 outbreaks, improving overall public health outcomes.
- 238 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
239 occupancy rates during dengue season will benefit from early outbreak fore-
240 casts that can help in managing patient inflow and ensuring adequate hos-
241 pital capacity.
- 242 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
243 able insights for researchers studying infectious disease patterns and policy-
244 makers focused on strengthening the national AI Roadmap. The system’s
245 data can support broader initiatives for sustainable health infrastructure
246 and inform policy decisions on resource allocation for dengue control.
- 247 • **Community Members:** By reducing the frequency and severity of outbreaks,
248 this study ultimately benefits the community at large. This allows for timely

249 awareness campaigns and community engagement initiatives, empowering
250 residents with knowledge and preventative measures to protect themselves
251 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

275 public health concern. Studies suggest that outbreak thresholds should be context-
276 specific, given the variability in transmission dynamics across different locations
277 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
278 Channel often base thresholds on 2 standard deviations (SD) above the mean
279 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
280 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
281 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
282 significantly across regions and time, making them inconsistent and incomparable.

283 From the studies above, this research implements an outbreak definition basing
284 the threshold on 2 standard deviations (SD) above the mean number of historic
285 dengue cases. It is important to note that for future outbreak definitions, addi-
286 tional local context like available hospital space etc., must be taken into account
287 for a more effective outbreak definition.

288 **2.3 Existing System: RabDash DC**

289 RabDash, developed by the University of the Philippines Mindanao, is a web-
290 based dashboard for rabies data analytics. It combines predictive modeling with
291 genomic data, enabling local health authorities to optimize interventions and al-
292 locate resources more effectively. RabDash’s modules include trend visualization,
293 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
294 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

295 For DengueWatch, RabDash serves as a strong inspiration, particularly in
296 its monitoring, historical trend visualization, and forecasting capabilities. These
297 features align well with the needs of dengue control efforts, providing real-time
298 insights into outbreak trends and enabling more effective, data-driven decision-
299 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
300 breaks similarly require time-series forecasting models. By using LSTM, RabDash
301 effectively models trends in outbreak data, which provides a framework for adapt-
302 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
303 form traditional methods, such as ARIMA and MLP, in handling the complexities
304 of time-dependent epidemiological data (Ligue & Ligue, 2022).

305 2.4 Deep Learning

306 The study of (Ligue & Ligue, 2022) highlights how data-driven models can help
307 predict dengue outbreaks. The authors compared traditional statistical meth-
308 ods, such as non-seasonal and seasonal autoregressive integrated moving average
309 (ARIMA), and traditional feed-forward network approach using a multilayer per-
310 ceptron (MLP) model with a deep learning approach using the long short-term
311 memory (LSTM) architecture in their prediction model. They found that the
312 LSTM model performs better in terms of accuracy. The LSTM model achieved a
313 much lower root mean square error (RMSE) compared to both MLP and ARIMA
314 models, proving its ability to capture complex patterns in time-series data (Ligue
315 & Ligue, 2022). This superior performance is attributed to LSTM’s capacity
316 to capture complex, time-dependent relationships within the data, such as those
317 between temperature, rainfall, humidity, and mosquito populations, all of which
318 contribute to dengue incidence (Ligue & Ligue, 2022).

319 2.5 Kalman Filter

320 The Kalman Filter is another powerful tool for time-series forecasting that can be
321 integrated into our analysis. It provides a recursive solution to estimating the state
322 of a linear dynamic system from a series of noisy measurements. Its application
323 in epidemiological modeling can enhance prediction accuracy by accounting for
324 uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters
325 are effective in predicting infectious disease outbreaks by refining estimates based
326 on observed data. A study published in *Frontiers in Physics* utilized the Kalman
327 filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman
328 filter effectively tracked the progression of deaths and cases, providing critical in-
329 sights for public health decision-making (Ahmadini et al., 2021). Another research
330 article in *PLOS ONE* focused on tracking the effective reproduction number (R_t)
331 of COVID-19 using a Kalman filter. This method estimated the growth rate of
332 new infections from noisy data, demonstrating that the Kalman filter could main-
333 tain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli,
334 Bullano, Kucinskas, & Rondón-Moreno, 2021).

335 Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM
336 models using our own collected dengue case data along with weather data to
337 identify the most effective model for real-time forecasting.

2.6 Weather Data

The relationship between weather patterns and mosquito-borne diseases is inherently nonlinear, meaning that fluctuations in disease cases do not respond proportionally to changes in climate variables (Colón-González, Fezzi, Lake, & Hunter, 2013). Weather data, such as minimum temperature and accumulated rainfall, are strongly linked to dengue case fluctuations, with effects observed after several weeks due to mosquito breeding and virus incubation cycles. Integrating these lagged weather effects into predictive models can improve early warning systems for dengue control (Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests that weather-based forecasting models using variables like mean temperature and cumulative rainfall can provide early warnings of dengue outbreaks with high sensitivity and specificity, enabling predictions up to 16 weeks in advance (Hii, Zhu, Ng, Ng, & Rocklöv, 2012).

We will utilize weather data, including variables such as temperature, rainfall, and humidity, as inputs for our dengue forecasting model. Given the strong, nonlinear relationship between climate patterns and dengue incidence, these weather variables, along with their lagged effects, are essential for enhancing prediction accuracy and providing timely early warnings for dengue outbreaks.

2.7 Chapter Summary

This chapter reviewed key literature relevant to our study, focusing on existing systems, predictive modeling techniques and the role of weather data in forecasting dengue outbreaks. We examined systems like RabDash DC, which integrates predictive modeling with real-time data to inform public health decisions, providing a foundational structure for our Dengue Watch System. Additionally, deep learning approaches, particularly Long Short-Term Memory (LSTM) networks, were highlighted for their effectiveness in time-series forecasting, while alternative methods such as ARIMA and Kalman Filters were considered for their ability to model complex temporal patterns and handle noisy data.

The literature further underscores the significance of weather variables—such as temperature and rainfall—in forecasting dengue cases. Studies demonstrate that these variables contribute to accurate outbreak prediction models. Leveraging these insights, our study will incorporate both weather data and historical dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

3.1 Research Activities

3.1.1 Gather Dengue Data and Climate Data to Create a Complete Dataset for Forecasting

Acquisition of Dengue Case Data

The historical dengue case dataset used in this study was obtained from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD) via Freedom of Information (FOI) requests. The decision to use weekly intervals was driven by the need for precision and timeliness in capturing fluctuations in dengue cases and weather conditions. Dengue transmission is influenced by short-term changes in weather variables such as rainfall and temperature, which impact mosquito breeding and virus transmission cycles. A weekly granularity allowed the model to better capture these short-term trends, enabling more accurate predictions and responsive public health interventions.

Moreover, using a weekly interval provided more data points for training the models compared to a monthly format. This is particularly critical in time series modeling, where larger datasets help improve the robustness of the model and its ability to generalize to new data. Also, the collection of weather data was done by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall, temperature, and humidity) from Weather Underground (wunderground.com).

Data Fields

- **Time.** Represents the specific year and week corresponding to each entry in the dataset.
- **Rainfall.** Denotes the observed average rainfall, measured in millimeters, for a specific week.
- **Humidity.** Refers to the observed average relative humidity, expressed as a percentage, for a specific week.
- **Max Temperature.** Represents the observed maximum temperature, measured in degrees Celsius, for a specific week.
- **Average Temperature.** Represents the observed average temperature, measured in degrees Celsius, for a specific week.

- 414 • **Min Temperature.** Represents the observed minimum temperature, mea-
415 sured in degrees Celsius, for a specific week.
- 416 • **Wind.** Represents the observed wind speed, measured in miles per hour
417 (mph), for a specific week.
- 418 • **Cases.** Refers to the number of reported dengue cases during a specific
419 week.

420 **Data Integration and Preprocessing**

421 The dengue case data was integrated with the weather data to create a com-
422 prehensive dataset, aligning the data based on corresponding timeframes. The
423 dataset underwent a cleaning process to address any missing values, outliers, and
424 inconsistencies to ensure its accuracy and reliability. To ensure that all features
425 and the target variable were on the same scale, a MinMaxScaler was applied to
426 normalize both the input features (climate data) and the target variable (dengue
427 cases).

428 **Exploratory Data Analysis (EDA)**

- 429 • Analyzed trends, seasonality, and correlations between dengue cases and
430 weather factors.
- 431 • Created visualizations like time series plots and scatterplots to highlight
432 relationships and patterns in the data.

433 **Outbreak Detection**

434 To detect outbreaks, we computed the outbreak threshold value of dengue cases
435 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

436 where μ is the historical mean and σ is the standard deviation.

437 3.1.2 Develop and Evaluate Deep Learning Models for 438 Dengue Case Forecasting

439 The deep learning models were developed and trained to forecast weekly dengue
440 cases using historical weather data (rainfall, temperature, wind, and humidity)
441 and dengue case counts. The dataset was normalized and divided into training and
442 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
443 for preparing and training the model are outlined below.

444 Data Preprocessing

445 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
446 ture, wind, humidity) and dengue case counts. The "Time" column was converted
447 to a datetime format to ensure proper temporal indexing. To standardize the data
448 for training, MinMaxScaler was employed, normalizing the feature values and tar-
449 get variable to a range of 0 to 1. This step ensured that the models could efficiently
450 process the data without being biased by feature scaling differences.

451 LSTM Model

452 The dataset was split into training and test sets to evaluate the model's perfor-
453 mance and generalizability:

- 454 • **Training Set:** 80% of the data (572 sequences) was used for model training,
455 enabling the LSTM to learn underlying patterns in historical dengue case
456 trends and their relationship with weather variables.
- 457 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
458 testing

459 To prepare the data for LSTM, a sliding window approach was utilized. Se-
460 quences of weeks of normalized features were constructed as input, while the
461 dengue case count for the subsequent week was set as the target variable. This
462 approach ensured that the model leveraged temporal dependencies in the data for
463 forecasting. To enhance the performance of the LSTM model in predicting dengue
464 cases, Bayesian Optimization was employed using the Keras Tuner library. The
465 tuning process aimed to minimize the validation loss (mean squared error) by
466 adjusting key model hyper-parameters. The search space is summarized below:

467 **LSTM units:**

- 468 • min value: 32
- 469 • max value: 128
- 470 • step: 16
- 471 • sampling: linear

472 **Learning Rate:**

- 473 • min value: 0.0001
- 474 • max value: 0.01
- 475 • step: None
- 476 • sampling: log

477 The tuner was instantiated with:

- 478 • **max trials = 10:** Limiting the search to 10 different configurations
- 479 • **executions per trial = 3:** Running each configuration thrice to reduce
480 variance
- 481 • **validation split = 0.2:** Reserving 20% of the training data for validation

482 The hyperparameter tuning was conducted for three different window sizes of
483 data: 5, 10, and 20. This allows the model to have the optimal hyperparameters
484 used for each window size. Training was conducted over 100 epochs with early
485 stopping to prevent overfitting while maintaining computational efficiency. A
486 batch size of 1 was used, enabling the model to process individual sequences,
487 which is suitable for smaller datasets but results in longer training times. The
488 Adam optimizer, known for its adaptive learning capabilities and stability was
489 employed.

490 To validate the effectiveness of the model, cross-validation was implemented.
491 However, standard k-fold cross-validation randomly shuffles the data, which isn't
492 suitable for time series since the order of observations is important. To address
493 this, a time series-specific cross-validation strategy was used with TimeSeriesS-
494 plit from the scikit-learn library. This method creates multiple train-test splits

495 where each training set expands over time and each test set follows sequentially.
496 This approach preserves the temporal structure of the data while helping reduce
497 overfitting by validating the model across different time segments.

498 After training, predictions on both the training and test datasets were rescaled
499 to their original scale using the inverse transformation of MinMaxScaler. Model
500 performance was evaluated using the mean squared error (MSE), root mean
501 squared error (RMSE) and mean absolute error (MAE).

502 **ARIMA**

503 The ARIMA model was utilized to forecast weekly dengue cases, leveraging histor-
504 ical weather data—including rainfall, maximum temperature, and humidity—as
505 exogenous variables alongside historical dengue case counts as the primary depen-
506 dent variable. The dataset was partitioned into training (80%) and testing (20%)
507 sets while maintaining temporal consistency.

508 To identify the optimal ARIMA configuration, a comprehensive grid search
509 was performed across the following parameter ranges:

- 510 • Autoregressive order (p): 0 to 3
- 511 • Differencing order (d): 0 to 2
- 512 • Moving average order (q): 0 to 3

513 Each combination of (p,d,q) was used to fit an ARIMA model, and perfor-
514 mance was evaluated based on the mean squared error (MSE) between the pre-
515 dicted and actual dengue cases on the test set. The parameter set that achieved
516 the lowest MSE was selected as the final model configuration.

517 Following model selection, the best-fit ARIMA model was retrained on the
518 training set and subsequently used to forecast dengue cases for the test period.
519 The predictions were assigned to the **PredictedCases** column in the test dataset.
520 Model performance was further assessed using key evaluation metrics, including
521 MSE, root mean squared error (RMSE), and mean absolute error (MAE). Visual
522 comparisons between actual and predicted dengue cases were produced through
523 line plots to better illustrate the model’s forecasting accuracy.

524 Seasonal ARIMA (SARIMA)

525 The SARIMA modeling process began with data preprocessing, which included
526 handling missing values through interpolation or imputation, and standardizing
527 features to ensure stable model training. The dataset was then split into training
528 and testing sets in an 80:20 ratio, preserving the temporal order of observations.
529 Seasonality analysis was conducted using time series decomposition and autocor-
530 relation plots, which revealed a periodicity of 52 weeks—justifying the adoption
531 of a seasonal model. To fine-tune the model, a grid search was performed over a
532 range of SARIMA parameters $(p,d,q)(P,D,Q)[S]$, while stationarity was validated
533 using the Augmented Dickey-Fuller (ADF) test. The model was then trained
534 on the dataset using rainfall, temperature, and humidity as exogenous variables,
535 with convergence ensured by setting a maximum number of iterations. Residual
536 diagnostics were used to confirm that residuals were uncorrelated, indicating a
537 good model fit. For evaluation, forecasts were compared against actual values,
538 and results were visualized with line plots. Finally, to validate the model’s gener-
539 alizability across different time periods, Time Series Cross-Validation with three
540 folds was applied. This allowed assessment of the model’s performance on multi-
541 ple time segments, providing insights into its robustness in real-world forecasting
542 scenarios.

543 Kalman Filter:

- 544 • Input Variables: The target variable (Cases) was modeled using three re-
545 gressors: rainfall, max temperature, and humidity.
- 546 • Training and Testing Split: The dataset was split into 80% training and
547 20% testing to evaluate model performance.
- 548 • Observation Matrix: The Kalman Filter requires an observation matrix,
549 which was constructed by adding an intercept (column of ones) to the re-
550 gressors.

551 The Kalman Filter’s Expectation-Maximization (EM) method was employed
552 for training, iteratively estimating model parameters over 10 iterations. After
553 training, the smoothing method was used to compute the refined state estimates
554 across the training data. Observation matrices for the test data were constructed
555 in the same manner as for the training set, ensuring compatibility with the learned
556 model parameters. On the test data, the Kalman Filter applied these parameters
557 to predict and correct the estimated dengue cases, providing more stable and
558 accurate forecasts compared to direct regression models. Additionally, a hybrid

559 Kalman Filter–LSTM (KF-LSTM) model was developed to combine the strengths
560 of both approaches. In this setup, the LSTM model was first used to predict
561 dengue cases based on historical data and weather features. The Kalman Filter
562 was then applied as a post-processing step to the LSTM predictions, smoothing
563 out noise and correcting potential errors.

564 **3.1.3 Integrate the Predictive Model into a Web-Based** 565 **Data Analytics Dashboard**

566 **Dashboard Design and Development**

- 567 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 568 – Interactive visualizations of yearly dengue case trends.
 - 569 – Data input and update forms for dengue and weather data.
 - 570 – Map display of dengue cases in each district in Iloilo City

571 **Model Integration and Deployment**

- 572 • Deploy the best-performing model within the dashboard as a backend service
573 to enable real-time or periodic forecasting.

574 **3.1.4 System Development Framework**

575 The Agile Model is the birthchild of both iterative and incremental approaches
576 in Software Engineering. It aims to be flexible and effective at the same time by
577 being adaptable to change. It's also important to note that small teams looking
578 to construct and develop projects quickly can benefit from this kind of method-
579 ology. As the Agile Method focuses on continuous testing, quality assurance is a
580 guarantee since bugs and errors are quickly identified and patched.

581 **3.1.5 Design, Building, Testing, and Integration**

582 **Design and Development**

583 After brainstorming and researching the most appropriate type of application to
584 accommodate both the prospected users and the proposed solutions, the team has

585 decided to proceed with a web application. Given the time constraints and avail-
586 able resources, we believe this is the most pragmatic and practical move. The next
587 step is to select modern and stable frameworks that align with the fundamental
588 ideas we have learned at the university. The template obtained from WVCHD
589 and Iloilo Provincial Epidemiology and Surveillance Unit was meticulously ana-
590 lyzed to create use cases and develop a preliminary well-structured database that
591 adheres to the requirements needed to produce a quality application. The said use
592 cases serve as the basis of general features. Part by part, these are converted into
593 code, and with the help of selected libraries and packages, it resulted in the de-
594 sired outcome that may still modified and extended since it is continuously being
595 developed.

596 **Testing and Integration**

597 Each feature will be rigorously user-tested to ensure quality assurance, with par-
598 ticular emphasis on prerequisite features, as development cannot progress properly
599 if these fail. Moreover, integration between each feature serves as a pillar for a
600 cohesive user experience. Presently, we have not been able to use performance
601 metrics to measure the system's performance, as developing and connecting the
602 core features is the utmost priority.

603 **3.2 Development Tools**

604 **3.2.1 Software**

605 **Github**

606 GitHub is a cloud-based platform that tracks file changes using Git, an open-
607 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
608 used in the project to store the application's source code, manage the system's
609 source version control, and serve as a repository for the Latex files used in the
610 actual research.

611 **Visual Studio Code**

612 Visual Studio Code is a free, lightweight, and cross-platform source code editor
613 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
614 this project’s programming and scripting languages, it was chosen as the primary
615 source code editor.

616 **Django**

617 Django is a free and open-sourced Python-based web framework that offers an
618 abstraction to develop and maintain a secure web application. As this research
619 aims to create a well-developed and maintainable application, it is in the best
620 interest to follow an architectural pattern that developers and contributors in the
621 future can understand. Since Django adheres to Model-View-Template (MVT)
622 that promotes a clean codebase by separating data models, business logic, and
623 presentation layers, it became the primary candidate for the application’s back-
624 bone.

625 **Next.js**

626 A report by Statista (2024) claims that React is the most popular front-end frame-
627 work among web developers. However, React has limitations that can be a nui-
628 sance in rapid software development, which includes routing and performance op-
629 timizations. This is where Next.js comes in—a framework built on top of React.
630 It offers solutions for React’s deficiency, making it a rising star in the framework
631 race.

632 **Postman**

633 As the application heavily relies on the Application Programming Interface (API)
634 being thrown by the backend, it is a must to use a development tool that facilitates
635 the development and testing of the API. Postman is a freemium API platform
636 that offers a user-friendly interface to create and manage API requests (*What is*
637 *Postman? Postman API Platform*, n.d.).

638 3.2.2 Hardware

639 The web application is continuously being developed on laptop computers with
640 minimum specifications of an 11th-generation Intel i5 CPU and 16 gigabytes of
641 RAM.

642 3.2.3 Packages

643 Django REST Framework

644 Django Rest Framework (DRF) is a third-party package for Django that provides a
645 comprehensive suite of features to simplify the development of robust and scalable
646 Web APIs (Christie, n.d.). These services include Serialization, Authentication
647 and Permissions, Viewsets and Routers, and a browsable API .

648 Leaflet

649 One of the features of the web application is the ability to map the number
650 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
651 most importantly, stable JavaScript package that can do the job. With its ultra-
652 lightweight size, it offers a comprehensive set of features that does not trade
653 off performance and usability (*Leaflet — an open-source JavaScript library for*
654 *interactive maps*, n.d.).

655 Chart.js

656 Another feature of the application is to provide users with informative, approach-
657 able data storytelling that is easy for everyone to understand. The transformation
658 of pure data points and statistics into figures such as charts is a big factor. Thus,
659 there is a need for a package that can handle this feature without compromising
660 the performance of the application. Chart.js is a free and open-source JavaScript
661 package that is made to meet this criteria as it supports various types of charts
662 (*Chart.js*, n.d.).

663 **Tailwind CSS**

664 Using plain CSS in production-quality applications can be counterproductive.
665 Therefore, CSS frameworks were developed to promote consistency and accelerate
666 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
667 which offers low-level utility classes that can be applied directly to each HTML
668 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
669 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
670 project, using this framework is a wise choice due to its stability and popularity
671 among developers.

672 **Shadcn**

673 Shadcn offers a collection of open-source UI boilerplate components that can be
674 directly copied and pasted into one's project. With the flexibility of the provided
675 components, Shadcn allows developers to have full control over customization and
676 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
677 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

678 **Zod**

679 Data validation is integral in this web application since it will handle crucial data
680 that will be used for analytical inferences and observations. Since Zod is primarily
681 used for validating and parsing data, it ensures proper communication between
682 the client and the server (Zod, n.d.).

3.3 Calendar of Activities

A Gantt chart showing the schedule of the activities is included below. Each bullet represents approximately one week of activity.

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. **Dengue Case Data:** The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. **Weather Data:** Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

704 4.2 Exploratory Data Analysis

705 From the summary above, the dataset consists of 720 weekly records with 8
706 columns:

- 707 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 708 • **Rainfall.** Weekly average rainfall (mm)
- 709 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
710 temperature data (C)
- 711 • **Wind.** Wind speed (m/s)
- 712 • **Humidity.** Weekly average humidity (%)
- 713 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks. To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

726 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 727 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

728

729 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 730 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 731 dengue cases. Notably, peak cases are observed during certain periods approx-
 732 imately 3 years, potentially aligning with specific climatic conditions such as
 733 increased rainfall or temperature changes. This underscores the importance of
 734 incorporating climate variables into the forecasting model.

735 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 736 and selected features, including rainfall, humidity, maximum temperature, aver-
 737 age temperature, minimum temperature, and wind speed. Among these, rainfall
 738 exhibits the highest positive correlation with dengue cases (correlation coefficient
 739 0.13), indicating that increased rainfall may contribute to higher cases counts.
 740 This aligns with existing studies suggesting that stagnant water from heavy rain-
 741 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 742 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 743 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 744 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 745 relationship than average and minimum temperature.

746 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 747 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

4.3 Outbreak Detection

To identify outbreaks, we calculated the outbreak threshold value using the historical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

where μ is the historical mean and σ is the standard deviation.

This result indicates that dengue cases exceeding 98 in Iloilo City can be considered an outbreak. However, it is important to note that this threshold serves only as a baseline. Additional parameters, such as the number of hospital beds available in the city, must be considered to compute a more effective threshold and develop an appropriate response strategy.

762 4.4 Model Training Results

763 The models were evaluated using three metrics: MSE, RMSE, and MAE. The
 764 table below provides a summary and comparative analysis of each model's results
 765 across these metrics, offering insights into the strengths and limitations of each
 766 forecasting technique for dengue case prediction in Iloilo City. The lower values
 767 of the three metrics indicate better forecasting performance. Table 4.1 shows that
 768 the models performed differently on testing data. LSTM outperformed the other
 769 models with the lowest RMSE, MSE, and MAE while the other three models had
 770 relatively higher values for the three metrics.

Method	LSTM	Seasonal ARIMA	ARIMA	Kalman Filter	KF-LSTM
Testing MSE	285.54	1261.20	1521.48	1474.82	785.35
Testing RMSE	16.90	34.45	39.00	38.40	25.56
Testing MAE	9.45	18.73	25.80	22.33	14.55
Best Parameters	Window Size: 5 Learning Rate: 0.01 Units: 64	(2,0,2)(0,1,1)	(1,2,2)	Observation Covariance: 10.0 Transition Covariance: $0.1 \times \text{Identity}$	Same as LSTM

Table 4.1: Comparison of different models for dengue prediction

771 4.4.1 LSTM Model

772 The LSTM model was tuned for the following parameters: learning rate and units.
 773 The hyperparameter tuning was conducted for each window size, finding the best
 774 parameters for each window size. Further evaluating which window size is most
 775 suitable for the prediction model, Table 4.2 shows the evaluation metrics for each
 window size used in the LSTM model training.

Window Size	MSE	RMSE	MAE	R ²
5	285.54	16.90	9.45	0.83
10	334.63	18.29	9.85	0.80
20	294.85	17.17	9.35	0.83

Table 4.2: Comparison of Window Sizes

776

777 The results indicate that a window size of 5 weeks provides the most accurate
 778 predictions, as evidenced by the lowest MSE and RMSE values. Furthermore, the
 779 R² score of 0.83 indicates that 83% of the variability in the target variable (cases)
 780 is explained by the independent variables (the inputs) in the model, making it a
 781 reliable configuration overall.

782 Figure 4.9 illustrates the model's performance in predicting dengue cases for
 783 each fold using a window size of 5. As shown in the plot, the training set progres-

784 sively increases with each fold, mimicking a real-world scenario where more data
 785 becomes available over time for dengue prediction. Figure 4.10 demonstrates that
 786 the predicted cases closely follow the trend of the actual cases, indicating that the
 787 LSTM model successfully captures the underlying patterns in the data. It is also
 788 evident that as the fold number increases and the training set grows, the accuracy
 789 of the predictions on the test set improves. Despite the test data being unseen,
 790 the model exhibits a strong ability to generalize, suggesting it effectively leverages
 791 past observations to predict future trends.

Figure 4.9: Training Folds - Window Size 5

Figure 4.10: Testing Folds - Window Size 5

792 4.4.2 ARIMA Model

Figure 4.11: ARIMA Prediction Results for Test Set

793 The ARIMA model was developed to capture non-seasonal trends in the data.
 794 To determine the best model configuration, grid search was used to explore vari-
 795 ous combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**.
 796 The model was iteratively refined over **400 iterations** to ensure convergence to
 797 an optimal solution. Figure 4.11 illustrates the comparison between actual and
 798 predicted dengue cases in the test set. As shown in the plot, the ARIMA model
 799 struggled to capture the non-linear characteristics and abrupt spikes in the data.
 800 Consequently, it failed to accurately reflect the fluctuations and outbreak patterns
 801 seen in the actual case counts.

802 The model's performance was assessed using regression metrics to evaluate its
 803 forecasting capability. The ARIMA model yielded the following error metrics:

- 804 • **MSE (Mean Squared Error):** 1521.48
- 805 • **RMSE (Root Mean Squared Error):** 39.01
- 806 • **MAE (Mean Absolute Error):** 25.80

4.4.3 Seasonal ARIMA (SARIMA) Model

To address the limitations of the ARIMA model, a Seasonal ARIMA (SARIMA) model was developed to capture both non-seasonal and seasonal variations in the data.

Figure 4.12: Seasonal ARIMA Prediction Results for Test Set

This model incorporates seasonal parameters, which were tuned using grid search to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA, **400 iterations** were applied to ensure a robust fit. As shown in Figure 4.12, the SARIMA model demonstrates a notable improvement in performance. Unlike its non-seasonal counterpart, it effectively captures the general trend and aligns more closely with the peaks observed in the actual dengue cases, indicating its ability to model seasonal dynamics.

The model's performance was assessed using regression metrics to evaluate its forecasting capability. The SARIMA model yielded the following error metrics:

- **MSE:** 1109.69
- **RMSE:** 33.31

822

- **MAE: 18.09**

823
824
825
826

The lower error values, when compared to the ARIMA model, highlight the SARIMA model's superior capability in forecasting dengue cases. Its effectiveness in capturing seasonal patterns contributed to a more accurate representation of the actual cases.

827
828
829
830
831
832

After training the model, the SARIMA model was validated using the same Time Series Cross-Validation strategy employed in the LSTM model. Table 4.3 presents the performance metrics for each fold, as well as the average metrics across all folds. The average RMSE and MAE values were close to those obtained during the initial training phase, indicating that the SARIMA model performed consistently across different time segments.

Fold	MSE	RMSE	MAE
1	659.68	25.68	16.00
2	2127.49	46.12	21.30
3	996.43	31.56	18.89
Average	1261.20	34.45	18.73

Table 4.3: Comparison of SARIMA performance for each fold

833

4.4.4 Kalman Filter Model

834
835
836
837
838
839
840
841

Figure 4.13 shows the comparison between the actual dengue cases and the predicted values on the test set. As illustrated in the plot, the Kalman Filter model demonstrates a moderate ability to follow the general trend of the actual data. While it effectively captures some rising and falling patterns, it still struggles to accurately replicate the sharp peaks and extreme values found in the real case counts. This limitation is particularly noticeable during the large spikes in 2022 and 2024. The model's performance was evaluated using standard regression metrics. The results are as follows:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

Figure 4.13: Kalman Filter Prediction Results for Test Set

842 The Kalman Filter was then combined with the LSTM model in order to see
843 improvements in its predictions. Table 4.4 shows the metrics across three folds
844 using the same Time Series Cross Validation Strategy employed in the previous
845 models to see how it performed on different time segments.

Fold	MSE	RMSE	MAE
1	113.59	10.66	6.42
2	752.51	27.43	12.11
3	1489.95	38.60	25.13
Average	785.35	25.56	14.55

Table 4.4: Comparison of KF-LSTM performance for each fold

846 As can be seen in the table above, the performance of the hybrid model demon-
847 strated improvements in all metrics as compared to just using the Kalman Filter
848 alone.

849 4.5 Preliminary System Requirements

850 4.5.1 Backend Requirements

851 Database Structure Design

852 Determining how data flows and how it would be structured is crucial in creating
 853 the system as it defines how extendible and flexible it would be for future features
 854 and updates. Thus, creating a comprehensive map of data ensures proper normal-
 855 ization that eliminates data redundancy and improves data integrity. Figure 4.14
 856 depicts the designed database schema that showcases the relationship between the
 857 application's entities.

Figure 4.14: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

858 4.5.2 User Interface Requirements

859 Admin Interface

Figure 4.15: Use Case Diagram for Admin

860 Figure 4.15 shows the possible tasks that the admin can do in the application. To
861 protect the integrity of data, only the admins can register and delete accounts.
862 Both account creation and deletion will be done within the application.

Figure 4.16: Use Case Diagram for Encoder

864 Figure 4.16, on the other hand, illustrates the use cases for the system's primary
865 users. Since only the admin accounts can register a user, the registration process
866 is not part of it. Instead, the main features, which include reporting and viewing
867 records, are the only permitted actions for this type of user. The said processes
868 can be done in the application by filling out a form with details required for each
869 dengue case. As data is entered, it will be consolidated for model training and
870 used for further forecasting of dengue cases.

871 4.5.3 Security and Validation Requirements

872 Password Encryption

873 Storing passwords as plain text in the database is a disgrace and a mortal sin in
874 production. It is important to implement precautionary methods such as hashing
875 and salting, followed by encryption with a strong algorithm, to prevent bad actors
876 from using the accounts for malicious transactions. By default, Django generates
877 a unique random salt for each password and encrypts it with Password-Based Key
878 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
879 techniques ensures that in the event of a data breach, cracking these passwords
880 would be time-consuming and useless for the attackers.

881 Authentication

882 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
883 the mechanism operates in a stateless manner, tokens are served only after a
884 successful login, eliminating the need for the server to keep a record of the token,
885 which is vulnerable to session hijacking. In addition, these tokens are signed with
886 a secret key, ensuring they have not been tampered with.

887 Data Validation

888 Both the backend and frontend should validate the input from the user to preserve
889 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
890 from the user. By doing this, the user can only send proper requests to the server
891 which streamlines the total workflow. On the other hand, Django has also a built-
892 in validator that checks the data type and ensures that the input matches the
893 expected format on the server side. These validation processes ensure that only
894 valid and properly formatted data is accepted, which reduces the risk of errors
895 and ensures consistency across the web application.

896 4.5.4 Testing Process

Figure 4.17: Testing Process for DengueWatch

897 As the system requirements and functionalities have been mentioned above, it
898 is important to implement testing to validate the system's performance and effi-
899 cacy. Since dengue reports include confidential information, anonymized historical
900 dengue reports were used to train the model and create the foundational architec-
901 ture of the system. By using functional tests, data validation and visualization can
902 be ensured for further continual improvements. Security testing is also important
903 as it is needed to safeguard confidential information when the system is deployed.
904 It includes proper authentication, permission views, and mitigating common in-
905 jection attacks. Finally, a user acceptance test from the prospected users, in this
906 case, the Iloilo City Epidemiology and Surveillance Unit, is crucial to assess its
907 performance and user experience. It enables the developers to confirm if the sys-
908 tem meets the needs of the problem, and once confirmed, it will be deployed and
909 further evaluated to ensure stability and reliability in live operation.

4.6 System Prototype

4.6.1 Guest Interface

The Guest Interface is intended for all visitors of the web application. It shows the related statistics for dengue cases in a particular area and time. As the system is still in its testing phase, the data converted into charts shown in Figure 4.18 are generated from Python's Faker library.

Figure 4.18: Dashboard for Guests

916 4.6.2 Personnel Interface

917 User Authentication, and Login

918 To protect the data's integrity in production, it has been decided that the registration process will not be visible. Instead, an admin must register a user using
919 a different interface. As of the moment, registering a user is done using API via
920 Postman. In the login process, the system implements HTTP-only cookies that
921 contains the JSON Web Tokens (JWT) to protect against XSS attacks. After
922 proper credentials have been provided, it will redirect to the user's home page.
923

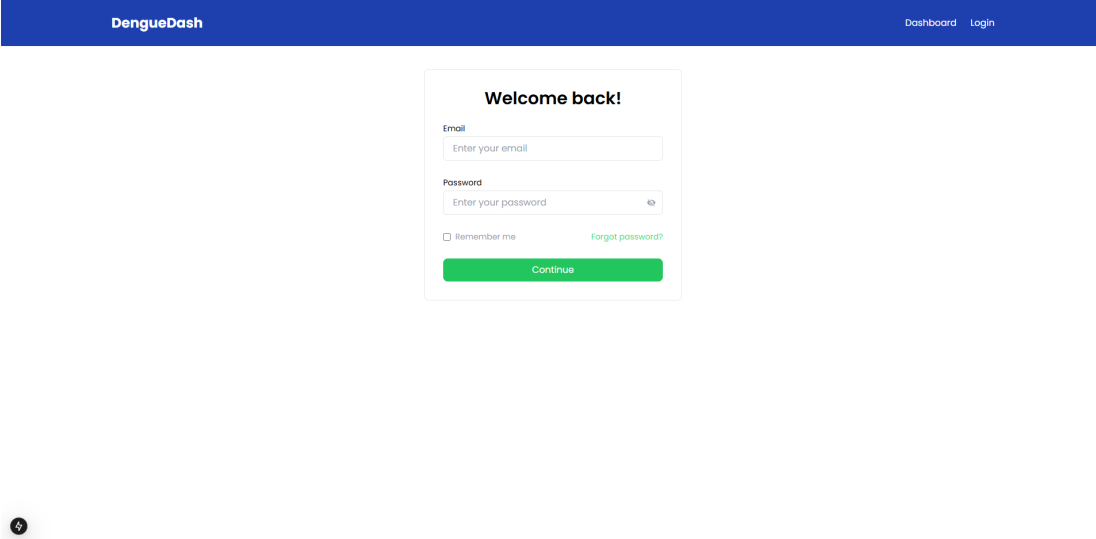

Figure 4.19: Login Page for Users

924 Encoder's View

925 Figures 4.20 and 4.21 show the digitized counterpart of the form obtained from the
926 Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to support
927 expandability for future features, some fields were modified to accommodate
928 more detailed input. It is worth noting that all of the included fields adhere to the
929 latest Philippine Integrated Disease and Surveillance Response (PIDSR) Dengue
930 Forms, which the referenced form was based on. By doing this, it is assumed
931 that the targeted users will have a familiarity when deployed on a national scale.
932 On a further note, the case form includes the patient's basic information, dengue
933 vaccination status, consultation details, laboratory results, and the outcome.

Figure 4.21: Second Part of Case Report Form

934 Once the data generated from the case report form is validated, it will be
 935 assigned as a new case and can be accessed through the Dengue Reports page, as
 936 shown in Figure 4.22. The said page displays basic information about the patient
 937 related to a specific case, including their name, address, date of consultation, and
 938 clinical and case classifications. It is also worth noting that it only shows cases
 939 the user is permitted to view. For example, in a local Disease Reporting Unit
 940 (DRU) setting, the user can only access records that came from the same DRU.
 941 On the other hand, in a consolidated surveillance unit such as a regional and
 942 provincial quarter, its users can view all the records that came from all the DRUs
 943 that report to them. Moving forward, Figure 4.23 shows the detailed case report
 944 of the patient on a particular consultation date.

The screenshot displays the DengueDash application. On the left is a sidebar menu with the following items: Analytics, Forms, Data Tables (expanded), Dengue Reports, Another Report, and Settings. The main content area is titled 'Building Your Application > Data Fetching' and contains a table of dengue reports. The table has columns for Case ID, Name, Barangay, City, Date Consulted, Clinical Classification, Case Classification, and Action. There are 12 rows of data, each with an 'Open' button in the Action column. At the bottom of the table, there is a pagination control showing '1' of 218 items.
