Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This study developed a centralized system for monitoring and modernizing data management of dengue cases in public health institutions, making it more efficient and acceptable. Using data gathered from the Iloilo Provincial Health Office and online sources, several deep learning models were trained to predict dengue cases, utilizing weather variables and historical case data as inputs. These models included Long Short-Term Memory (LSTM), ARIMA, Seasonal ARIMA, Kalman Filter (KF), and a hybrid KF-LSTM model. The models underwent time series cross-validation strategies to mimic real-world conditions as closely as possible and were evaluated using metrics such as Mean Squared Error (MSE), Root Mean Squared Error (RMSE), and Mean Absolute Error (MAE). The LSTM model demonstrated the best performance with the lowest RMSE of 16.90, followed by the hybrid KF-LSTM model at 25.56. The LSTM model was then integrated into the system to provide forecasting features that could support health institutions by offering actionable insights for proactive intervention strategies.

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

171 This study explores the monitoring and forecasting of dengue outbreaks by an-
172 alyzing key factors such as temperature, relative humidity, and historical dengue
173 cases, using different models. The findings aim to provide an advanced, AI-driven
174 alternative for dengue prevention and control, targeting agencies like the Depart-
175 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
176 in Iloilo City, this research aspires to improve outbreak responses through cutting-
177 edge technology rather than traditional reporting methods.

178 1.2 Problem Statement

179 Dengue remains a critical public health challenge worldwide, with cases increasing
180 due to the easing of COVID-19 restrictions and heightened global mobility. While
181 a temporary decline in cases was observed during the pandemic (2020–2022) due
182 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
183 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
184 regions like the Philippines, the threat is particularly severe. In Iloilo City and
185 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
186 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
187 pital beds occupied by dengue patients, highlighting the urgent need for effective
188 predictive tools. The lack of a reliable system to monitor and forecast dengue
189 outbreaks contributes to delayed interventions, exacerbating public health risks
190 and healthcare burdens in the region.

191 1.3 Research Objectives

192 1.3.1 General Objective

193 This study aims to develop an AI-based dengue forecasting and monitoring system
194 for Iloilo City and Province. The researchers will train and compare multiple deep
195 learning models to predict dengue case trends based on climate data and historical
196 dengue cases to help public health officials in possible dengue case outbreaks.

197 1.3.2 Specific Objectives

198 Specifically, this study aims to:

- 199 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
200 (including temperature, rainfall, wind, and humidity) from online sources.
201 Combine and aggregate these data into a unified dataset to facilitate com-
202 prehensive dengue case forecasting.
- 203 2. Evaluate deep learning models for predicting dengue cases using metrics
204 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
205 and Mean Squared Error (MSE). Compare the performance of these models
206 to determine the most accurate forecasting approach.
- 207 3. Develop a web-based analytics dashboard that integrates a predictive model
208 and provides data management system for dengue cases in Iloilo City and
209 the Province.
- 210 4. Assess the usability and effectiveness of the analytics dashboard through
211 structured feedback and surveys involving health professionals and policy-
212 makers.

213 1.4 Scope and Limitations of the Research

214 This study aims to gather dengue data from the Iloilo Provincial Health Office
215 and climate data from online sources such as PAGASA or weatherandclimate.com.
216 These data will be preprocessed, cleaned, and combined into a unified dataset to
217 facilitate comprehensive dengue case forecasting. However, the study is limited by
218 the availability and completeness of historical data. Inconsistent or missing data
219 points may introduce biases and reduce the quality of predictions. Furthermore,
220 the granularity of the data will be in a weekly format.

221 To evaluate deep learning models for predicting dengue cases, the study will
222 train and compare the performance of various models, using metrics like Mean
223 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
224 aim to provide accurate forecasts, their performance is heavily influenced by the
225 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
226 predictions. Additionally, the models cannot fully account for external factors
227 such as public health interventions or socio-economic conditions which may impact
228 dengue transmission dynamics.

229 The study also involves developing a web-based analytics dashboard that in-
230 tegrates predictive models and provides a data management system for dengue
231 cases in Iloilo City and the Province. This dashboard will offer public health
232 officials an interactive interface to visualize dengue trends, input new data, and

233 identify risk areas. However, its usability depends on feedback from stakeholders,
234 which may vary based on their familiarity with analytics tools. Moreover, exter-
235 nal factors such as limited internet connectivity or device availability in remote
236 areas may affect the system’s adoption and effectiveness. While the dashboard
237 provides valuable insights, it cannot incorporate all factors influencing dengue
238 transmission, emphasizing the need for ongoing validation and refinement.

239 1.5 Significance of the Research

240 This study’s development of an AI-based dengue forecasting and monitoring sys-
241 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 242 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
243 and local health units in Iloilo City and Province stand to benefit greatly
244 from the system. With dengue predictions, we can help these agencies opti-
245 mize their response strategies and implement targeted prevention measures
246 in high-risk areas before cases escalate.
- 247 • **Local Government Units (LGUs):** LGUs can use the system to support
248 their disaster management and health initiatives by proactively addressing
249 dengue outbreaks. The predictive insights allow for more efficient planning
250 and resource deployment in barangays and communities most vulnerable to
251 outbreaks, improving overall public health outcomes.
- 252 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
253 occupancy rates during dengue season will benefit from early outbreak fore-
254 casts that can help in managing patient inflow and ensuring adequate hos-
255 pital capacity.
- 256 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
257 able insights for researchers studying infectious disease patterns and policy-
258 makers focused on strengthening the national AI Roadmap. The system’s
259 data can support broader initiatives for sustainable health infrastructure
260 and inform policy decisions on resource allocation for dengue control.
- 261 • **Community Members:** By reducing the frequency and severity of outbreaks,
262 this study ultimately benefits the community at large. This allows for timely

263 awareness campaigns and community engagement initiatives, empowering
264 residents with knowledge and preventative measures to protect themselves
265 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

289 public health concern. Studies suggest that outbreak thresholds should be context-
290 specific, given the variability in transmission dynamics across different locations
291 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
292 Channel often base thresholds on 2 standard deviations (SD) above the mean
293 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
294 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
295 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
296 significantly across regions and time, making them inconsistent and incomparable.

297 From the studies above, this research implements an outbreak definition basing
298 the threshold on 2 standard deviations (SD) above the mean number of historic
299 dengue cases. It is important to note that for future outbreak definitions, addi-
300 tional local context like available hospital space etc., must be taken into account
301 for a more effective outbreak definition.

302 **2.3 Existing System: RabDash DC**

303 RabDash, developed by the University of the Philippines Mindanao, is a web-
304 based dashboard for rabies data analytics. It combines predictive modeling with
305 genomic data, enabling local health authorities to optimize interventions and al-
306 locate resources more effectively. RabDash’s modules include trend visualization,
307 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
308 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

309 For DengueWatch, RabDash serves as a strong inspiration, particularly in
310 its monitoring, historical trend visualization, and forecasting capabilities. These
311 features align well with the needs of dengue control efforts, providing real-time
312 insights into outbreak trends and enabling more effective, data-driven decision-
313 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
314 breaks similarly require time-series forecasting models. By using LSTM, RabDash
315 effectively models trends in outbreak data, which provides a framework for adapt-
316 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
317 form traditional methods, such as ARIMA and MLP, in handling the complexities
318 of time-dependent epidemiological data (Ligue & Ligue, 2022).

319 2.4 Deep Learning

320 The study of (Ligue & Ligue, 2022) highlights how data-driven models can help
321 predict dengue outbreaks. The authors compared traditional statistical meth-
322 ods, such as non-seasonal and seasonal autoregressive integrated moving average
323 (ARIMA), and traditional feed-forward network approach using a multilayer per-
324 ceptron (MLP) model with a deep learning approach using the long short-term
325 memory (LSTM) architecture in their prediction model. They found that the
326 LSTM model performs better in terms of accuracy. The LSTM model achieved a
327 much lower root mean square error (RMSE) compared to both MLP and ARIMA
328 models, proving its ability to capture complex patterns in time-series data (Ligue
329 & Ligue, 2022). This superior performance is attributed to LSTM’s capacity
330 to capture complex, time-dependent relationships within the data, such as those
331 between temperature, rainfall, humidity, and mosquito populations, all of which
332 contribute to dengue incidence (Ligue & Ligue, 2022).

333 2.5 Kalman Filter

334 The Kalman Filter is another powerful tool for time-series forecasting that can be
335 integrated into our analysis. It provides a recursive solution to estimating the state
336 of a linear dynamic system from a series of noisy measurements. Its application
337 in epidemiological modeling can enhance prediction accuracy by accounting for
338 uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters
339 are effective in predicting infectious disease outbreaks by refining estimates based
340 on observed data. A study published in *Frontiers in Physics* utilized the Kalman
341 filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman
342 filter effectively tracked the progression of deaths and cases, providing critical in-
343 sights for public health decision-making (Ahmadini et al., 2021). Another research
344 article in *PLOS ONE* focused on tracking the effective reproduction number (R_t)
345 of COVID-19 using a Kalman filter. This method estimated the growth rate of
346 new infections from noisy data, demonstrating that the Kalman filter could main-
347 tain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli,
348 Bullano, Kucinskas, & Rondón-Moreno, 2021).

349 Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM
350 models using our own collected dengue case data along with weather data to
351 identify the most effective model for real-time forecasting.

2.6 Weather Data

The relationship between weather patterns and mosquito-borne diseases is inherently nonlinear, meaning that fluctuations in disease cases do not respond proportionally to changes in climate variables (Colón-González, Fezzi, Lake, & Hunter, 2013). Weather data, such as minimum temperature and accumulated rainfall, are strongly linked to dengue case fluctuations, with effects observed after several weeks due to mosquito breeding and virus incubation cycles. Integrating these lagged weather effects into predictive models can improve early warning systems for dengue control (Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests that weather-based forecasting models using variables like mean temperature and cumulative rainfall can provide early warnings of dengue outbreaks with high sensitivity and specificity, enabling predictions up to 16 weeks in advance (Hii, Zhu, Ng, Ng, & Rocklöv, 2012).

We will utilize weather data, including variables such as temperature, rainfall, and humidity, as inputs for our dengue forecasting model. Given the strong, nonlinear relationship between climate patterns and dengue incidence, these weather variables, along with their lagged effects, are essential for enhancing prediction accuracy and providing timely early warnings for dengue outbreaks.

2.7 Chapter Summary

This chapter reviewed key literature relevant to our study, focusing on existing systems, predictive modeling techniques and the role of weather data in forecasting dengue outbreaks. We examined systems like RabDash DC, which integrates predictive modeling with real-time data to inform public health decisions, providing a foundational structure for our Dengue Watch System. Additionally, deep learning approaches, particularly Long Short-Term Memory (LSTM) networks, were highlighted for their effectiveness in time-series forecasting, while alternative methods such as ARIMA and Kalman Filters were considered for their ability to model complex temporal patterns and handle noisy data.

The literature further underscores the significance of weather variables—such as temperature and rainfall—in forecasting dengue cases. Studies demonstrate that these variables contribute to accurate outbreak prediction models. Leveraging these insights, our study will incorporate both weather data and historical dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

3.1 Research Activities

3.1.1 Gather Dengue Data and Climate Data to Create a Complete Dataset for Forecasting

Acquisition of Dengue Case Data

The historical dengue case dataset used in this study was obtained from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD) via Freedom of Information (FOI) requests. The decision to use weekly intervals was driven by the need for precision and timeliness in capturing fluctuations in dengue cases and weather conditions. Dengue transmission is influenced by short-term changes in weather variables such as rainfall and temperature, which impact mosquito breeding and virus transmission cycles. A weekly granularity allowed the model to better capture these short-term trends, enabling more accurate predictions and responsive public health interventions.

Moreover, using a weekly interval provided more data points for training the models compared to a monthly format. This is particularly critical in time series modeling, where larger datasets help improve the robustness of the model and its ability to generalize to new data. Also, the collection of weather data was done by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall, temperature, and humidity) from Weather Underground (wunderground.com).

Data Fields

- **Time.** Represents the specific year and week corresponding to each entry in the dataset.
- **Rainfall.** Denotes the observed average rainfall, measured in millimeters, for a specific week.
- **Humidity.** Refers to the observed average relative humidity, expressed as a percentage, for a specific week.
- **Max Temperature.** Represents the observed maximum temperature, measured in degrees Celsius, for a specific week.
- **Average Temperature.** Represents the observed average temperature, measured in degrees Celsius, for a specific week.

- 428 • **Min Temperature.** Represents the observed minimum temperature, mea-
429 sured in degrees Celsius, for a specific week.
- 430 • **Wind.** Represents the observed wind speed, measured in miles per hour
431 (mph), for a specific week.
- 432 • **Cases.** Refers to the number of reported dengue cases during a specific
433 week.

434 Data Integration and Preprocessing

435 The dengue case data was integrated with the weather data to create a com-
436 prehensive dataset, aligning the data based on corresponding timeframes. The
437 dataset underwent a cleaning process to address any missing values, outliers, and
438 inconsistencies to ensure its accuracy and reliability. To ensure that all features
439 and the target variable were on the same scale, a MinMaxScaler was applied to
440 normalize both the input features (climate data) and the target variable (dengue
441 cases).

442 Exploratory Data Analysis (EDA)

- 443 • Analyzed trends, seasonality, and correlations between dengue cases and
444 weather factors.
- 445 • Created visualizations like time series plots and scatterplots to highlight
446 relationships and patterns in the data.

447 Outbreak Detection

448 To detect outbreaks, we computed the outbreak threshold value of dengue cases
449 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

450 where μ is the historical mean and σ is the standard deviation.

451 3.1.2 Develop and Evaluate Deep Learning Models for 452 Dengue Case Forecasting

453 The deep learning models were developed and trained to forecast weekly dengue
454 cases using historical weather data (rainfall, temperature, wind, and humidity)
455 and dengue case counts. The dataset was normalized and divided into training and
456 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
457 for preparing and training the model are outlined below.

458 Data Preprocessing

459 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
460 ture, wind, humidity) and dengue case counts. The "Time" column was converted
461 to a datetime format to ensure proper temporal indexing. To standardize the data
462 for training, MinMaxScaler was employed, normalizing the feature values and tar-
463 get variable to a range of 0 to 1. This step ensured that the models could efficiently
464 process the data without being biased by feature scaling differences.

465 LSTM Model

466 The dataset was split into training and test sets to evaluate the model's perfor-
467 mance and generalizability:

- 468 • **Training Set:** 80% of the data (572 sequences) was used for model training,
469 enabling the LSTM to learn underlying patterns in historical dengue case
470 trends and their relationship with weather variables.
- 471 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
472 testing

473 To prepare the data for LSTM, a sliding window approach was utilized. Se-
474 quences of weeks of normalized features were constructed as input, while the
475 dengue case count for the subsequent week was set as the target variable. This
476 approach ensured that the model leveraged temporal dependencies in the data for
477 forecasting. To enhance the performance of the LSTM model in predicting dengue
478 cases, Bayesian Optimization was employed using the Keras Tuner library. The
479 tuning process aimed to minimize the validation loss (mean squared error) by
480 adjusting key model hyper-parameters. The search space is summarized below:

481 **LSTM units:**

- 482 • min value: 32
- 483 • max value: 128
- 484 • step: 16
- 485 • sampling: linear

486 **Learning Rate:**

- 487 • min value: 0.0001
- 488 • max value: 0.01
- 489 • step: None
- 490 • sampling: log

491 The tuner was instantiated with:

- 492 • **max trials = 10:** Limiting the search to 10 different configurations
- 493 • **executions per trial = 3:** Running each configuration thrice to reduce
494 variance
- 495 • **validation split = 0.2:** Reserving 20% of the training data for validation

496 The hyperparameter tuning was conducted for three different window sizes of
497 data: 5, 10, and 20. This allows the model to have the optimal hyperparameters
498 used for each window size. Training was conducted over 100 epochs with early
499 stopping to prevent overfitting while maintaining computational efficiency. A
500 batch size of 1 was used, enabling the model to process individual sequences,
501 which is suitable for smaller datasets but results in longer training times. The
502 Adam optimizer, known for its adaptive learning capabilities and stability was
503 employed.

504 To validate the effectiveness of the model, cross-validation was implemented.
505 However, standard k-fold cross-validation randomly shuffles the data, which isn't
506 suitable for time series since the order of observations is important. To address
507 this, a time series-specific cross-validation strategy was used with TimeSeriesS-
508 plit from the scikit-learn library. This method creates multiple train-test splits

509 where each training set expands over time and each test set follows sequentially.
510 This approach preserves the temporal structure of the data while helping reduce
511 overfitting by validating the model across different time segments.

512 After training, predictions on both the training and test datasets were rescaled
513 to their original scale using the inverse transformation of MinMaxScaler. Model
514 performance was evaluated using the mean squared error (MSE), root mean
515 squared error (RMSE) and mean absolute error (MAE).

516 **ARIMA**

517 The ARIMA model was utilized to forecast weekly dengue cases, leveraging histor-
518 ical weather data—including rainfall, maximum temperature, and humidity—as
519 exogenous variables alongside historical dengue case counts as the primary depen-
520 dent variable. The dataset was partitioned into training (80%) and testing (20%)
521 sets while maintaining temporal consistency.

522 To identify the optimal ARIMA configuration, a comprehensive grid search
523 was performed across the following parameter ranges:

- 524 • Autoregressive order (p): 0 to 3
- 525 • Differencing order (d): 0 to 2
- 526 • Moving average order (q): 0 to 3

527 Each combination of (p,d,q) was used to fit an ARIMA model, and perfor-
528 mance was evaluated based on the mean squared error (MSE) between the pre-
529 dicted and actual dengue cases on the test set. The parameter set that achieved
530 the lowest MSE was selected as the final model configuration.

531 Following model selection, the best-fit ARIMA model was retrained on the
532 training set and subsequently used to forecast dengue cases for the test period.
533 The predictions were assigned to the **PredictedCases** column in the test dataset.
534 Model performance was further assessed using key evaluation metrics, including
535 MSE, root mean squared error (RMSE), and mean absolute error (MAE). Visual
536 comparisons between actual and predicted dengue cases were produced through
537 line plots to better illustrate the model’s forecasting accuracy.

538 Seasonal ARIMA (SARIMA)

539 The SARIMA modeling process began with data preprocessing, which included
540 handling missing values through interpolation or imputation, and standardizing
541 features to ensure stable model training. The dataset was then split into training
542 and testing sets in an 80:20 ratio, preserving the temporal order of observations.
543 Seasonality analysis was conducted using time series decomposition and autocor-
544 relation plots, which revealed a periodicity of 52 weeks—justifying the adoption
545 of a seasonal model. To fine-tune the model, a grid search was performed over a
546 range of SARIMA parameters $(p,d,q)(P,D,Q)[S]$, while stationarity was validated
547 using the Augmented Dickey-Fuller (ADF) test. The model was then trained
548 on the dataset using rainfall, temperature, and humidity as exogenous variables,
549 with convergence ensured by setting a maximum number of iterations. Residual
550 diagnostics were used to confirm that residuals were uncorrelated, indicating a
551 good model fit. For evaluation, forecasts were compared against actual values,
552 and results were visualized with line plots. Finally, to validate the model’s gener-
553 alizability across different time periods, Time Series Cross-Validation with three
554 folds was applied. This allowed assessment of the model’s performance on multi-
555 ple time segments, providing insights into its robustness in real-world forecasting
556 scenarios.

557 Kalman Filter:

- 558 • Input Variables: The target variable (Cases) was modeled using three re-
559 gressors: rainfall, max temperature, and humidity.
- 560 • Training and Testing Split: The dataset was split into 80% training and
561 20% testing to evaluate model performance.
- 562 • Observation Matrix: The Kalman Filter requires an observation matrix,
563 which was constructed by adding an intercept (column of ones) to the re-
564 gressors.

565 The Kalman Filter’s Expectation-Maximization (EM) method was employed
566 for training, iteratively estimating model parameters over 10 iterations. After
567 training, the smoothing method was used to compute the refined state estimates
568 across the training data. Observation matrices for the test data were constructed
569 in the same manner as for the training set, ensuring compatibility with the learned
570 model parameters. On the test data, the Kalman Filter applied these parameters
571 to predict and correct the estimated dengue cases, providing more stable and
572 accurate forecasts compared to direct regression models. Additionally, a hybrid

573 Kalman Filter–LSTM (KF-LSTM) model was developed to combine the strengths
574 of both approaches. In this setup, the LSTM model was first used to predict
575 dengue cases based on historical data and weather features. The Kalman Filter
576 was then applied as a post-processing step to the LSTM predictions, smoothing
577 out noise and correcting potential errors.

578 **3.1.3 Integrate the Predictive Model into a Web-Based** 579 **Data Analytics Dashboard**

580 **Dashboard Design and Development**

- 581 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 582 – Interactive visualizations of yearly dengue case trends.
 - 583 – Data input and update forms for dengue and weather data.
 - 584 – Map display of dengue cases in each district in Iloilo City

585 **Model Integration and Deployment**

- 586 • Deploy the best-performing model within the dashboard as a backend service
587 to enable real-time or periodic forecasting.

588 **3.1.4 System Development Framework**

589 The Agile Model is the birthchild of both iterative and incremental approaches
590 in Software Engineering. It aims to be flexible and effective at the same time by
591 being adaptable to change. It's also important to note that small teams looking
592 to construct and develop projects quickly can benefit from this kind of method-
593 ology. As the Agile Method focuses on continuous testing, quality assurance is a
594 guarantee since bugs and errors are quickly identified and patched.

595 **Design and Development**

596 After brainstorming and researching the most appropriate type of application to
597 accommodate both the prospected users and the proposed solutions, the team
598 has decided to proceed with a web application. Given the time constraints and
599 available resources, it has been decided that the said means is the most pragmatic

600 and practical move. The next step is to select modern and stable frameworks
 601 that align with the fundamental ideas learned by the researchers in the university.
 602 The template obtained from WVCHD and Iloilo Provincial Epidemiology and
 603 Surveillance Unit was meticulously analyzed to create use cases and develop a
 604 preliminary well-structured database that adheres to the requirements needed
 605 to produce a quality application. The said use cases serve as the basis of general
 606 features. Part by part, these are converted into code, and with the help of selected
 607 libraries and packages, it resulted in the desired outcome that may still modified
 608 and extended to achieve scalability.

609 Testing and Integration

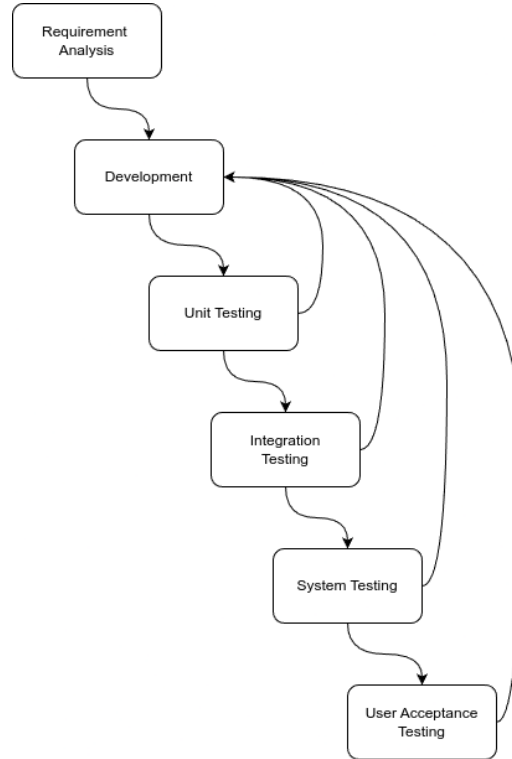

Figure 3.2: Testing Process for DengueWatch

610 Implementing testing is important to validate the system's performance and ef-
 611 ficacy. Thus a series of tests were conducted to identify and resolve bugs during
 612 the developmental phase. Each feature was rigorously tested to ensure quality as-
 613 surance, with particular emphasis on prerequisite features, as development cannot
 614 progress properly if these fail. Because of this, integration between each feature

615 serves as a pillar for a cohesive user experience. Since dengue reports include
616 confidential information, anonymized historical dengue reports were used to train
617 the model and create the foundational architecture of the system. By using func-
618 tional tests, data validation and visualization can be ensured for further continual
619 improvements. Security testing is also important as it is needed to safeguard
620 confidential information when the system is deployed. It includes proper authen-
621 tication, permission views, and mitigating common injection attacks. Finally, a
622 user acceptance test from the prospected users, in this case, doctors, nurses, and
623 other health workers is crucial to assess its performance and user experience. It
624 enables the developers to confirm if the system meets the needs of the problem.

625 **3.2 Development Tools**

626 **3.2.1 Software**

627 **Github**

628 GitHub is a cloud-based platform that tracks file changes using Git, an open-
629 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
630 used in the project to store the application’s source code, manage the system’s
631 source version control, and serve as a repository for the Latex files used in the
632 actual research.

633 **Visual Studio Code**

634 Visual Studio Code is a free, lightweight, and cross-platform source code editor
635 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
636 this project’s programming and scripting languages, it was chosen as the primary
637 source code editor.

638 **Django**

639 Django is a free and open-sourced Python-based web framework that offers an
640 abstraction to develop and maintain a secure web application. As this research
641 aims to create a well-developed and maintainable application, it is in the best
642 interest to follow an architectural pattern that developers and contributors in the

643 future can understand. Since Django adheres to Model-View-Template (MVT)
644 that promotes a clean codebase by separating data models, business logic, and
645 presentation layers, it became the primary candidate for the application’s back-
646 bone.

647 **Next.js**

648 A report by Statista (2024) claims that React is the most popular front-end frame-
649 work among web developers. However, React has limitations that can be a nui-
650 sance in rapid software development, which includes routing and performance op-
651 timizations. This is where Next.js comes in—a framework built on top of React.
652 It offers solutions for React’s deficiency, making it a rising star in the framework
653 race.

654 **Postman**

655 As the application heavily relies on the Application Programming Interface (API)
656 being thrown by the backend, it is a must to use a development tool that facilitates
657 the development and testing of the API. Postman is a freemium API platform
658 that offers a user-friendly interface to create and manage API requests (*What is*
659 *Postman? Postman API Platform*, n.d.).

660 **3.2.2 Hardware**

661 The web application was developed on laptop computers with minimum specifica-
662 tions of an 11th-generation Intel i5 CPU and 16 gigabytes of RAM. Furthermore,
663 an RTX 3060 mobile GPU was also utilized to retrain the integrated model locally.

664 **3.2.3 Packages**

665 **Django REST Framework**

666 Django Rest Framework (DRF) is a third-party package for Django that provides a
667 comprehensive suite of features to simplify the development of robust and scalable
668 Web APIs (Christie, n.d.). These services include Serialization, Authentication
669 and Permissions, Viewsets and Routers, and a browsable API .

670 Leaflet

671 One of the features of the web application is the ability to map the number
672 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
673 most importantly, stable JavaScript package that can do the job. With its ultra-
674 lightweight size, it offers a comprehensive set of features that does not trade
675 off performance and usability (*Leaflet — an open-source JavaScript library for*
676 *interactive maps*, n.d.).

677 Chart.js

678 Another feature of the application is to provide users with informative, approach-
679 able data storytelling that is easy for everyone to understand. The transformation
680 of pure data points and statistics into figures such as charts is a big factor. Thus,
681 there is a need for a package that can handle this feature without compromising
682 the performance of the application. Chart.js is a free and open-source JavaScript
683 package that is made to meet this criteria as it supports various types of charts
684 (*Chart.js*, n.d.).

685 Tailwind CSS

686 Using plain CSS in production-quality applications can be counterproductive.
687 Therefore, CSS frameworks were developed to promote consistency and accelerate
688 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
689 which offers low-level utility classes that can be applied directly to each HTML
690 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
691 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
692 project, using this framework is a wise choice due to its stability and popularity
693 among developers.

694 Shadcn

695 Shadcn offers a collection of open-source UI boilerplate components that can be
696 directly copied and pasted into one's project. With the flexibility of the provided
697 components, Shadcn allows developers to have full control over customization and
698 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
699 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

700 **Zod**

701 Data validation is integral in this web application since it will handle crucial data
702 that will be used for analytical inferences and observations. Since Zod is primarily
703 used for validating and parsing data, it ensures proper communication between
704 the client and the server (Zod, n.d.).

705 3.3 Application Requirements

706 3.3.1 Backend Requirements

707 Database Structure Design

708 Determining how data flows and how it would be structured is crucial in creating
709 the system as it defines how extendible and flexible it would be for future features
710 and updates. Thus, creating a comprehensive map of data ensures proper nor-
711 malization that eliminates data redundancy and improves data integrity. Figure
712 3.3 depicts the designed database schema that showcases the relationship between
713 the application's entities.

Figure 3.3: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

3.3.2 User Interface Requirements

Admin Interface

Figure 3.4: Use Case Diagram for Admins

Figure 3.4 shows the actions of an admin for a specific Disease Reporting Unit (DRU) and an admin for a specific Surveillance Unit can take in the application. Both of them include the management of accounts, browsing records, and forecasting and retraining all the consolidated data under their supervision. Most

720 importantly, these users must verify the encoders who register under their ju-
 721 risdiction before allowing their account to access the application in the name of
 722 safeguarding the integrity of the data. The only advantage of the latter type of ad-
 723 ministrator is that it has a one-step higher authorization as it manages the DRUs.
 724 In addition, only the authorized surveillance unit administrator can register and
 725 create a DRU to uphold transparency and accountability.

726 Encoder Interface

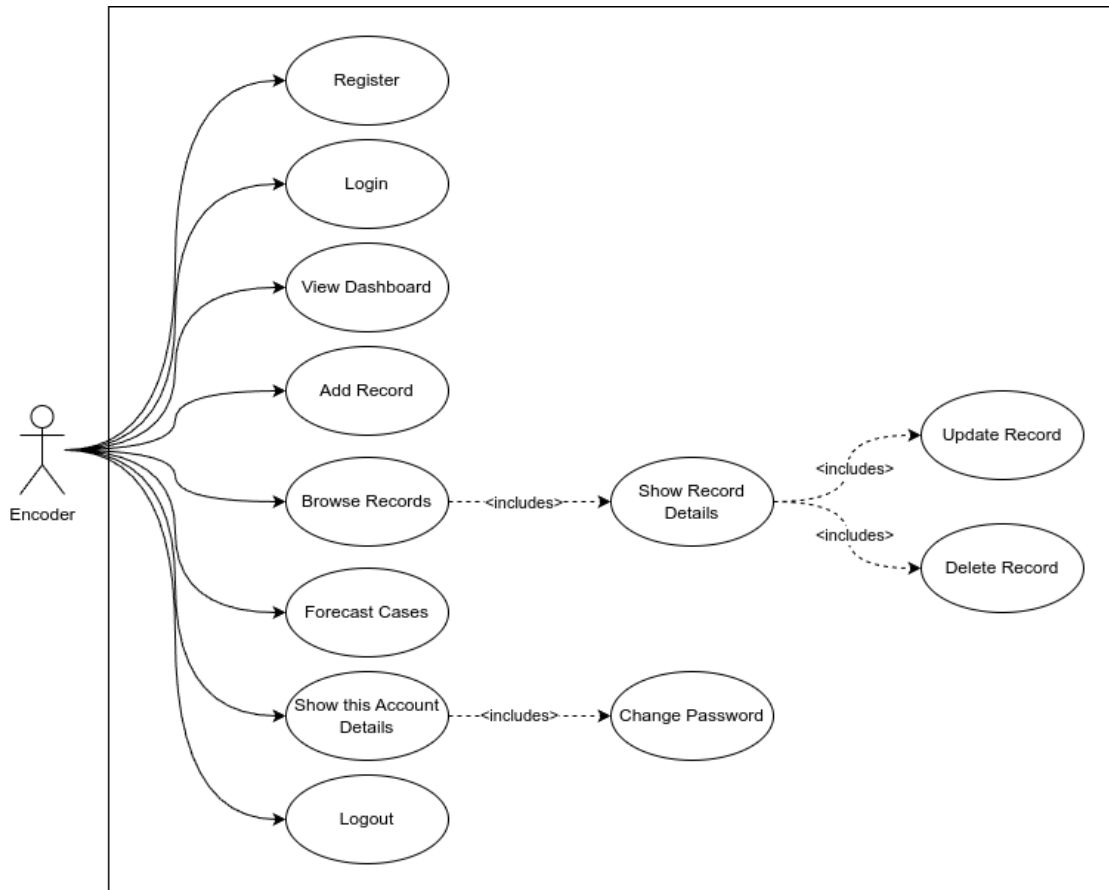

Figure 3.5: Use Case Diagram for Encoder

727 Figure 3.5, on the other hand, illustrates the use cases for the system's primary
 728 users. These users can register but must wait for further verification to access the
 729 application. Similar to the previous interfaces, encoders can browse and manage
 730 records, as well as forecast the consolidated cases under a specific surveillance or
 731 disease reporting unit, but they are not allowed to retrain the model. Lastly, they

732 are the only type of user that can file and create dengue cases by filling out a form
733 with the required details.

734 **3.3.3 Security and Validation Requirements**

735 **Password Encryption**

736 Storing passwords as plain text in the database is a disgrace and a mortal sin in
737 production. It is important to implement precautionary methods such as hashing
738 and salting, followed by encryption with a strong algorithm, to prevent bad actors
739 from using the accounts for malicious transactions. By default, Django generates
740 a unique random salt for each password and encrypts it with Password-Based Key
741 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
742 techniques ensures that in the event of a data breach, cracking these passwords
743 would be time-consuming and useless for the attackers.

744 **Authentication**

745 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
746 the mechanism operates in a stateless manner, tokens are served only after a
747 successful login, eliminating the need for the server to keep a record of the token,
748 which is vulnerable to session hijacking. In addition, these tokens are signed with
749 a secret key, ensuring they have not been tampered with.

750 **Data Validation**

751 Both the backend and frontend should validate the input from the user to preserve
752 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
753 from the user. By doing this, the user can only send proper requests to the server
754 which streamlines the total workflow. On the other hand, Django has also a built-
755 in validator that checks the data type and ensures that the input matches the
756 expected format on the server side. These validation processes ensure that only
757 valid and properly formatted data is accepted, which reduces the risk of errors
758 and ensures consistency across the web application.

3.4 Calendar of Activities

A Gantt chart showing the schedule of the activities is included below. Each bullet represents approximately one week of activity.

Table 3.1: Timetable of Activities for 2024

Activities	Aug	Sept	Oct	Nov	Dec

Integrate the Best Model to the System	•	••••			
Extend Features to Accommodate a National Setting		•	••		
User Testing			••	•	
Documentation	••	••••	••••	••••	••••

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. Dengue Case Data: The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. Weather Data: Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

```
data.head()
```

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases
0	2011-01-03	9.938571	29.444400	25.888890	23.888900	11.39	86.242857	5

780 4.2 Exploratory Data Analysis

781 From the summary above, the dataset consists of 720 weekly records with 8
782 columns:

- 783 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 784 • **Rainfall.** Weekly average rainfall (mm)
- 785 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
786 temperature data (C)
- 787 • **Wind.** Wind speed (m/s)
- 788 • **Humidity.** Weekly average humidity (%)
- 789 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks.

To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

802 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 803 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

804

805 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 806 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 807 dengue cases. Notably, peak cases are observed during certain periods approx-
 808 imately 3 years, potentially aligning with specific climatic conditions such as
 809 increased rainfall or temperature changes. This underscores the importance of
 810 incorporating climate variables into the forecasting model.

811 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 812 and selected features, including rainfall, humidity, maximum temperature, aver-
 813 age temperature, minimum temperature, and wind speed. Among these, rainfall
 814 exhibits the highest positive correlation with dengue cases (correlation coefficient
 815 0.13), indicating that increased rainfall may contribute to higher cases counts.
 816 This aligns with existing studies suggesting that stagnant water from heavy rain-
 817 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 818 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 819 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 820 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 821 relationship than average and minimum temperature.

822 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 823 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

4.3 Outbreak Detection

To identify outbreaks, we calculated the outbreak threshold value using the historical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

where μ is the historical mean and σ is the standard deviation.

This result indicates that dengue cases exceeding 98 in Iloilo City can be considered an outbreak. However, it is important to note that this threshold serves only as a baseline. Additional parameters, such as the number of hospital beds available in the city, must be considered to compute a more effective threshold and develop an appropriate response strategy.

838 4.4 Model Training Results

839 The models were evaluated using three metrics: MSE, RMSE, and MAE. The
 840 table below provides a summary and comparative analysis of each model's results
 841 across these metrics, offering insights into the strengths and limitations of each
 842 forecasting technique for dengue case prediction in Iloilo City. The lower values
 843 of the three metrics indicate better forecasting performance. Table 4.1 shows that
 844 the models performed differently on testing data. LSTM outperformed the other
 845 models with the lowest RMSE, MSE, and MAE while the other three models had
 846 relatively higher values for the three metrics.

Method	LSTM	Seasonal ARIMA	ARIMA	Kalman Filter	KF-LSTM
Testing MSE	285.54	1261.20	1521.48	1474.82	785.35
Testing RMSE	16.90	34.45	39.00	38.40	25.56
Testing MAE	9.45	18.73	25.80	22.33	14.55
Best Parameters	Window Size: 5 Learning Rate: 0.01 Units: 64	(2,0,2)(0,1,1)	(1,2,2)	Observation Covariance: 10.0 Transition Covariance: $0.1 \times \text{Identity}$	Same as LSTM

Table 4.1: Comparison of different models for dengue prediction

847 4.4.1 LSTM Model

848 The LSTM model was tuned for the following parameters: learning rate and units.
 849 The hyperparameter tuning was conducted for each window size, finding the best
 850 parameters for each window size. Further evaluating which window size is most
 851 suitable for the prediction model, Table 4.2 shows the evaluation metrics for each
 window size used in the LSTM model training.

Window Size	MSE	RMSE	MAE	R ²
5	285.54	16.90	9.45	0.83
10	334.63	18.29	9.85	0.80
20	294.85	17.17	9.35	0.83

Table 4.2: Comparison of Window Sizes

852

853 The results indicate that a window size of 5 weeks provides the most accurate
 854 predictions, as evidenced by the lowest MSE and RMSE values. Furthermore, the
 855 R² score of 0.83 indicates that 83% of the variability in the target variable (cases)
 856 is explained by the independent variables (the inputs) in the model, making it a
 857 reliable configuration overall.

858 Figure 4.9 illustrates the model's performance in predicting dengue cases for
 859 each fold using a window size of 5. As shown in the plot, the training set progres-

860 sively increases with each fold, mimicking a real-world scenario where more data
861 becomes available over time for dengue prediction. Figure 4.10 demonstrates that
862 the predicted cases closely follow the trend of the actual cases, indicating that the
863 LSTM model successfully captures the underlying patterns in the data. It is also
864 evident that as the fold number increases and the training set grows, the accuracy
865 of the predictions on the test set improves. Despite the test data being unseen,
866 the model exhibits a strong ability to generalize, suggesting it effectively leverages
867 past observations to predict future trends.

Figure 4.9: Training Folds - Window Size 5

Figure 4.10: Testing Folds - Window Size 5

868 4.4.2 ARIMA Model

Figure 4.11: ARIMA Prediction Results for Test Set

869 The ARIMA model was developed to capture non-seasonal trends in the data.
 870 To determine the best model configuration, grid search was used to explore vari-
 871 ous combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**.
 872 The model was iteratively refined over **400 iterations** to ensure convergence to
 873 an optimal solution. Figure 4.11 illustrates the comparison between actual and
 874 predicted dengue cases in the test set. As shown in the plot, the ARIMA model
 875 struggled to capture the non-linear characteristics and abrupt spikes in the data.
 876 Consequently, it failed to accurately reflect the fluctuations and outbreak patterns
 877 seen in the actual case counts.

878 The model's performance was assessed using regression metrics to evaluate its
 879 forecasting capability. The ARIMA model yielded the following error metrics:

- 880 • **MSE (Mean Squared Error):** 1521.48
- 881 • **RMSE (Root Mean Squared Error):** 39.01
- 882 • **MAE (Mean Absolute Error):** 25.80

4.4.3 Seasonal ARIMA (SARIMA) Model

To address the limitations of the ARIMA model, a Seasonal ARIMA (SARIMA) model was developed to capture both non-seasonal and seasonal variations in the data.

Figure 4.12: Seasonal ARIMA Prediction Results for Test Set

This model incorporates seasonal parameters, which were tuned using grid search to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA, **400 iterations** were applied to ensure a robust fit. As shown in Figure 4.12, the SARIMA model demonstrates a notable improvement in performance. Unlike its non-seasonal counterpart, it effectively captures the general trend and aligns more closely with the peaks observed in the actual dengue cases, indicating its ability to model seasonal dynamics.

The model's performance was assessed using regression metrics to evaluate its forecasting capability. The SARIMA model yielded the following error metrics:

- **MSE:** 1109.69
- **RMSE:** 33.31

898

- **MAE: 18.09**

899 The lower error values, when compared to the ARIMA model, highlight the
 900 SARIMA model's superior capability in forecasting dengue cases. Its effective-
 901 ness in capturing seasonal patterns contributed to a more accurate representation
 902 of the actual cases.

903 After training the model, the SARIMA model was validated using the same
 904 Time Series Cross-Validation strategy employed in the LSTM model. Table 4.3
 905 presents the performance metrics for each fold, as well as the average metrics
 906 across all folds. The average RMSE and MAE values were close to those obtained
 907 during the initial training phase, indicating that the SARIMA model performed
 908 consistently across different time segments.

Fold	MSE	RMSE	MAE
1	659.68	25.68	16.00
2	2127.49	46.12	21.30
3	996.43	31.56	18.89
Average	1261.20	34.45	18.73

Table 4.3: Comparison of SARIMA performance for each fold

909 4.4.4 Kalman Filter Model

910 Figure 4.13 shows the comparison between the actual dengue cases and the pre-
 911 dicted values on the test set. As illustrated in the plot, the Kalman Filter model
 912 demonstrates a moderate ability to follow the general trend of the actual data.
 913 While it effectively captures some rising and falling patterns, it still struggles to
 914 accurately replicate the sharp peaks and extreme values found in the real case
 915 counts. This limitation is particularly noticeable during the large spikes in 2022
 916 and 2024. The model's performance was evaluated using standard regression met-
 917 rics. The results are as follows:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

Figure 4.13: Kalman Filter Prediction Results for Test Set

918 The Kalman Filter was then combined with the LSTM model in order to see
 919 improvements in its predictions. Table 4.4 shows the metrics across three folds
 920 using the same Time Series Cross Validation Strategy employed in the previous
 921 models to see how it performed on different time segments.

Fold	MSE	RMSE	MAE
1	113.59	10.66	6.42
2	752.51	27.43	12.11
3	1489.95	38.60	25.13
Average	785.35	25.56	14.55

Table 4.4: Comparison of KF-LSTM performance for each fold

922 As can be seen in the table above, the performance of the hybrid model demon-
 923 strated improvements in all metrics as compared to just using the Kalman Filter
 924 alone.

4.5 Model Simulation

To evaluate the LSTM model’s real-world forecasting ability, a simulation was conducted to predict dengue cases for the year 2025. The model was trained exclusively on data from 2011 to 2024, using both dengue cases and weather variables. Importantly, the actual dengue case values for 2025 were never included during training. Instead, only the weather variables collected for 2025 were input into the model to generate predictions for that year. After prediction, the forecasted dengue cases for 2025 were compared against the true observed cases to assess the model’s accuracy. Figure 4.14 shows that the predicted values closely follow the trend, although it may overestimate the dengue cases in some weeks.

Figure 4.14: Predicted vs Actual Dengue Cases 2025

4.6 System Prototype

4.6.1 Home Page

The Home Page is intended for all visitors of the web application. The Analytics Dashboard, which displays relevant statistics for dengue cases at a certain year and location, is the primary component highlighted, as seen in Figure 4.15. This component includes a combo chart that graphs the number of dengue cases and deaths per week in a specific year, a choropleth map that tracks the number of

942 dengue cases per location, and various bar charts that indicate the top locations
943 affected by dengue.

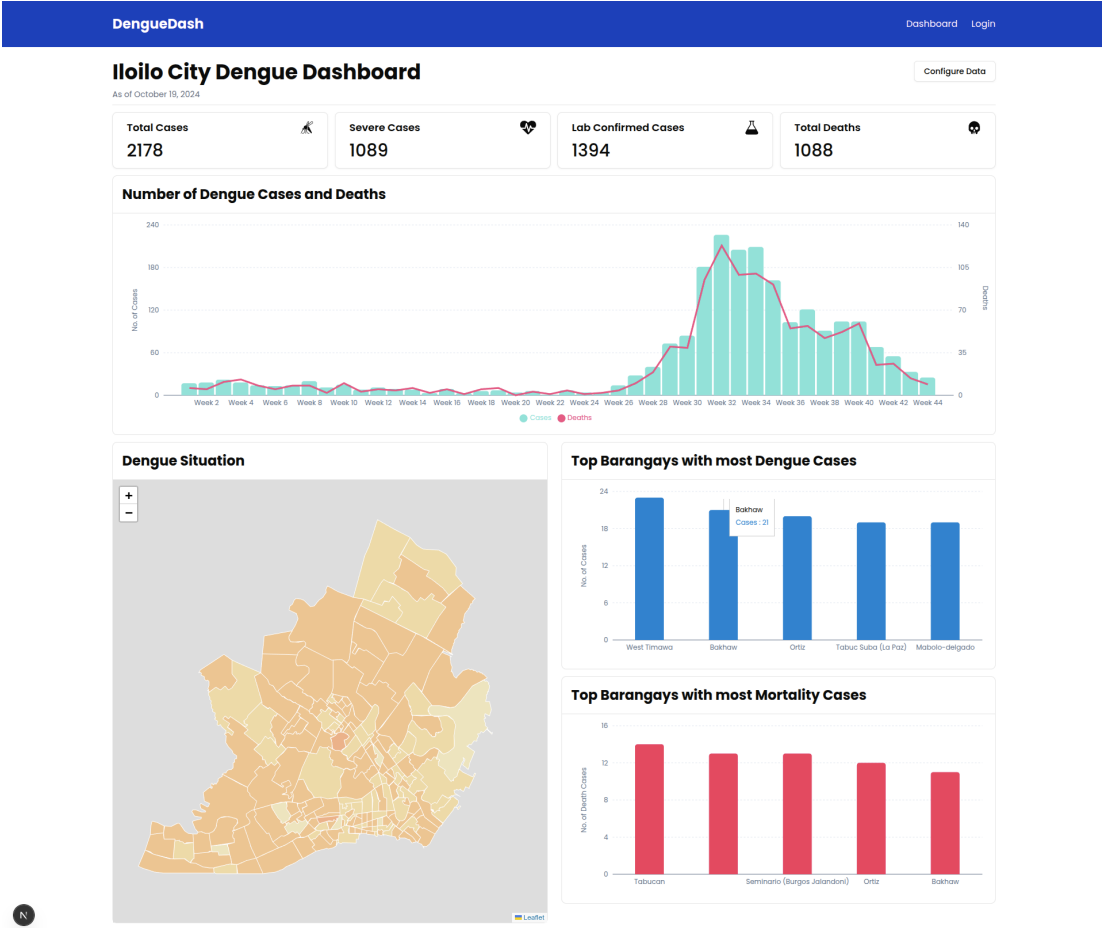

Figure 4.15: Home Page

944 **4.6.2 User Registration, Login, and Authentication**

945 The registration page, as shown in Figure 4.16, serves as a gateway to access the
946 authenticated pages of the web application. Only prospected encoders can create
947 an account since administrator accounts are only made by existing administra-
948 tor accounts to protect the data's integrity in production. After registering, the
949 "encoder account" cannot access the authorized pages yet as it needs to be veri-
950 fied first by an administrator managing the unit the user entered. Once verified,
951 the user can log in to the system through the page shown in Figure 4.17. Af-
952 ter entering the correct credentials, which consist of an email and password, the

953 system uses HTTP-only cookies containing JSON Web Tokens (JWT) to prevent
954 vulnerability to Cross-site Scripting (XSS) attacks. It will then proceed to the
955 appropriate page the type of user belongs to.

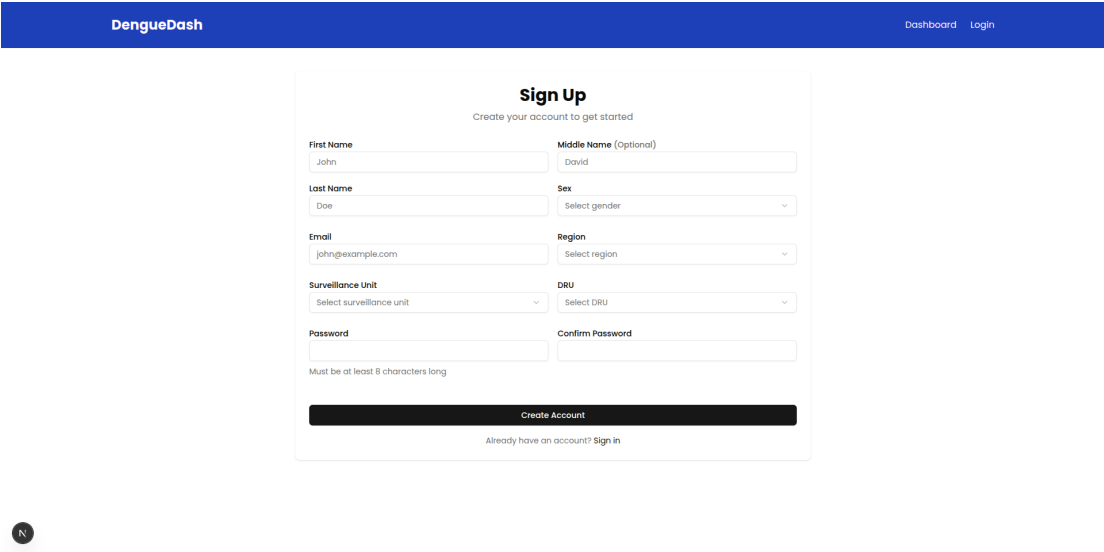

Figure 4.16: Sign Up Page

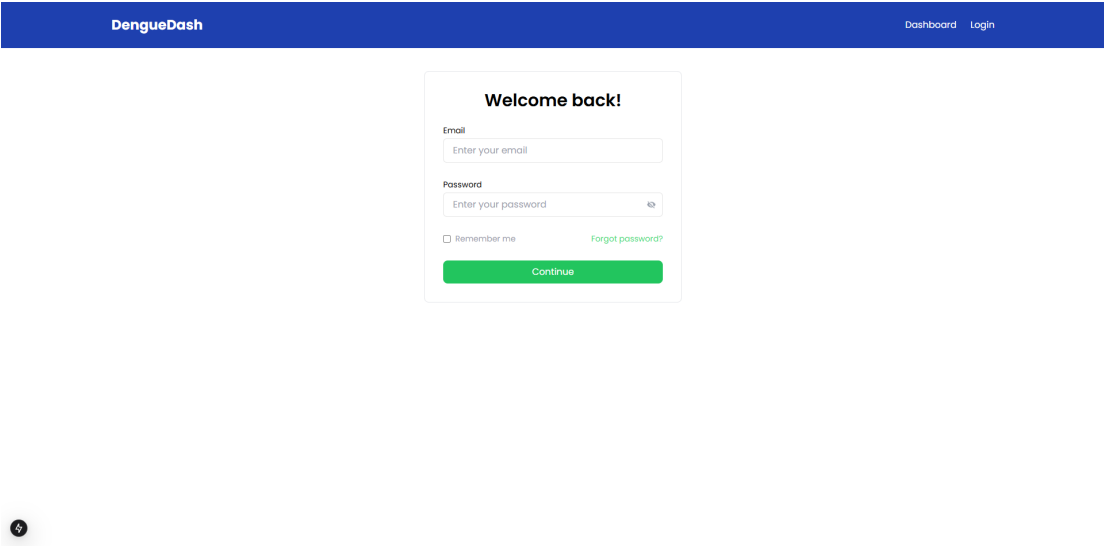

Figure 4.17: Login Page

4.6.3 Encoder Interface

Case Report Form

Figures 4.18 and 4.19 show the digitized counterpart of the form obtained from the Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to support expandability for future features, some fields were modified to accommodate more detailed input. It is worth noting that all of the included fields adhere to the latest Philippine Integrated Disease and Surveillance Response (PIDS) Dengue Forms, which the referenced form was based on. By doing this, if implemented on a national scale, the transition between targeted users will be easier. Moreover, the case form includes the patient's basic information, dengue vaccination status, consultation details, laboratory results, and the outcome. On the other hand, encoders can also create case records using a "bulk upload" feature that makes use of a formatted CSV file template. As shown in Figure 4.20, an encoder can download the template using the "Download Template" button, and insert multiple records inside the file, then upload it by clicking the "Click to upload" button. The web application automatically checks the file for data inconsistencies and validation.

The screenshot displays the 'Case Report Form' interface within the 'DengueDash' application. The interface is organized into two main columns: 'Personal Information' and 'Clinical Status'. The 'Personal Information' column contains a 'Personal Detail' section with fields for First Name, Middle Name, Last Name, Suffix, Sex, Civil Status, Date of Birth, and Address. The 'Address' section includes fields for Region, Province, City, Barangay, Street, and House No. Below this is a 'Vaccination' section with fields for Date of First Vaccination and Date of Last Vaccination. The 'Clinical Status' column is currently empty. A 'Bulk Upload' button is located in the top right corner. The user's name 'Elizabeth Thomas Ra...' and email 'elwis@example.com' are displayed in the bottom left corner.

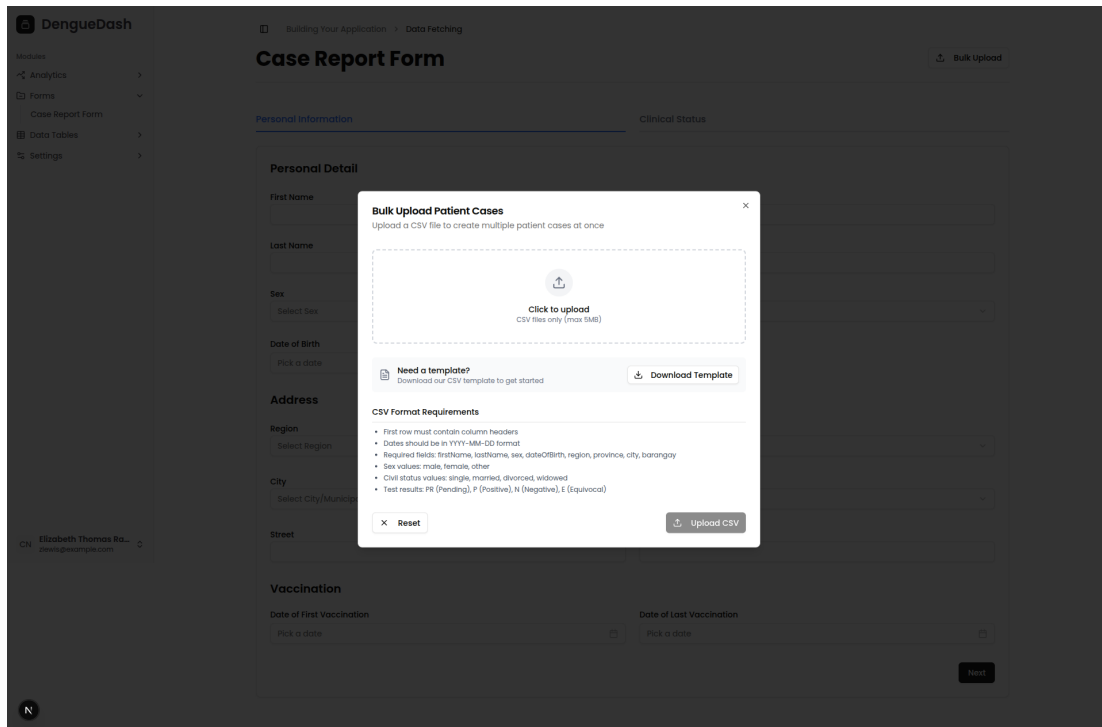

Figure 4.20: Bulk Upload of Cases using CSV

973 Browsing, Update, and Deletion of Records

974 Once the data generated from the case report form or the bulk upload is vali-
 975 dated, it will be assigned as a new case and can be accessed through the Dengue
 976 Reports page, as shown in Figure 4.21. The said page displays basic information
 977 about the patient related to a specific case, including their name, address, date
 978 of consultation, and clinical and case classifications. It is also worth noting that
 979 it only shows cases the user is permitted to view. For example, in a local Disease
 980 Reporting Unit (DRU) setting, the user can only access records that belong to
 981 the same DRU. On the other hand, in a consolidated surveillance unit such as a
 982 regional, provincial, or city quarter, its users can view all the records from all the
 983 DRUs that report to them. Moving forward, Figure 4.22 shows the detailed case
 984 report of the patient on a particular consultation date.

Figure 4.24: Delete Report Alert Dialog

993 **Forecasting**

994 The main highlight of the web application’s feature is the Forecasting Page. This
995 is where users can forecast dengue cases for the next following weeks. To predict,
996 the application utilizes the exported LSTM model in a Keras format derived
997 from training the consolidated data from the database. It requires the recent
998 weekly dengue cases, weather variable data (temperature, humidity, and rainfall)
999 based on the window size, and future weather data through OpenWeatherMap
1000 API. However, due to limitations imposed in the current plan subscribed in the
1001 API, only the next 16 days of weather data can be fetched. As a result, the web
1002 application can only make a two-week prediction. Moving forward, the Forecasting
1003 page, as shown in Figure 4.25, introduces a user-friendly interface that shows the

1004 current cases for the week, and the predictions for the next two weeks with a range
1005 of 90 percent to 110 percent confidence interval that is presented in a simple but
1006 organized manner. There is also a line chart that shows the number of cases from
1007 the last 5 weeks plus the forecasted weekly cases. In addition, the current weather
1008 data for a specific week is also shown as well as the the forecasted weather data
1009 fetched from the said API. Lastly, locations where dengue cases have been reported
1010 for the current week are listed in the Location Risk Assessment component.

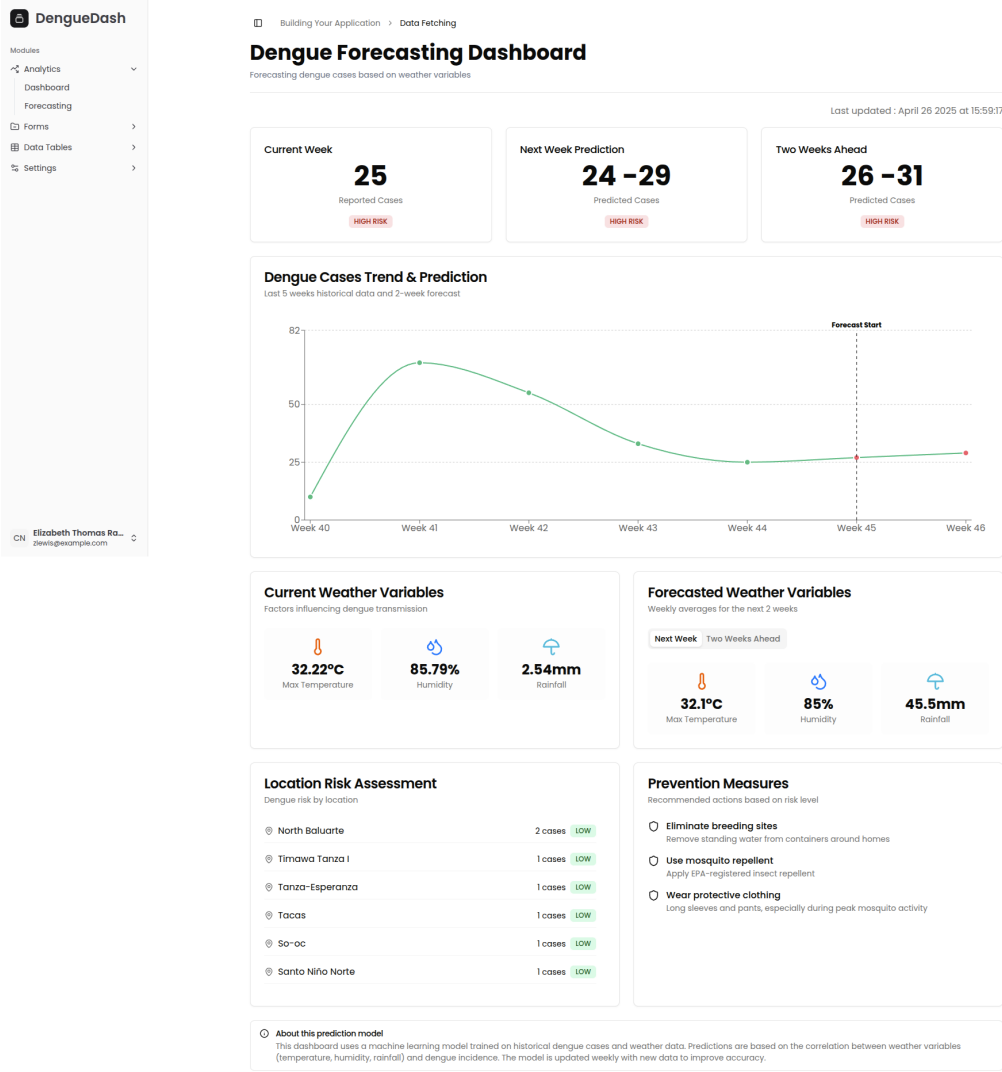

Figure 4.25: Forecasting Page

1011 **4.6.4 Admin Interface**

1012 **Retraining**

1013 With LSTM being the best-performing model among the models used in forecast-
1014 ing dengue cases, it is the model chosen to power the prediction and retraining
1015 of the consolidated data within the web application. Since the retraining process
1016 consumes a lot of processing power and requires a more advanced understanding
1017 of how it works, it was decided that the said feature should only be available
1018 to admin users. Furthermore, the retraining component in the Forecasting page
1019 includes three additional components that include the configuration of LSTM pa-
1020 rameters (Figure 4.26), the actual retraining of the consolidated data from the
1021 database (Figure 4.27), and the results of the retraining that shows the current
1022 and previous model metrics depending on the parameters entered (Figure 4.28).
1023 It is also worth noting that when trained, the model used a seeded number to
1024 promote reproducibility.

1025 **Managing Accounts**

1026 Proper management of accounts is important to protect the integrity and confi-
1027 dentiality of data. Thus, it is crucial for administrators to track their users and
1028 control the flow of information. As discussed in the user registration of encoders,
1029 admin users from a specific DRU or surveillance have the power to grant them ac-
1030 cess to the web application. Figure 4.30 illustrates the interface for this scenario,
1031 as the admins can approve or reject their applications. Once approved, these users
1032 can access the features given to encoders and may be promoted to have admin-
1033 istrative access, as shown in Figure 4.31. When deleting an account, the user’s
1034 email will be blacklisted and illegible to use when creating another account, and
1035 all the cases reported by this user will be soft-deleted. The same figure also shows
1036 the expanded details of the user, which include personal information and brief
1037 activity details within the system.

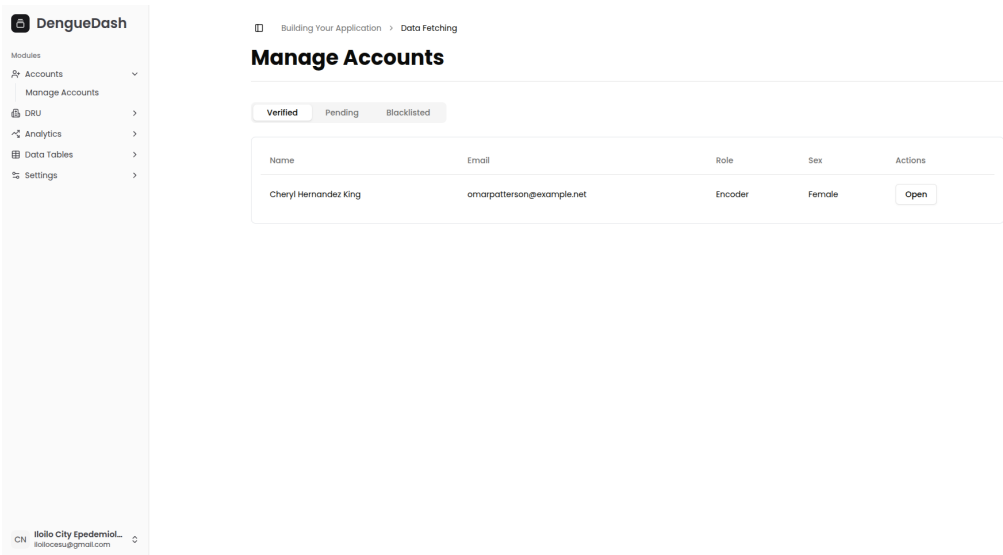

Figure 4.29: List of Verified Accounts

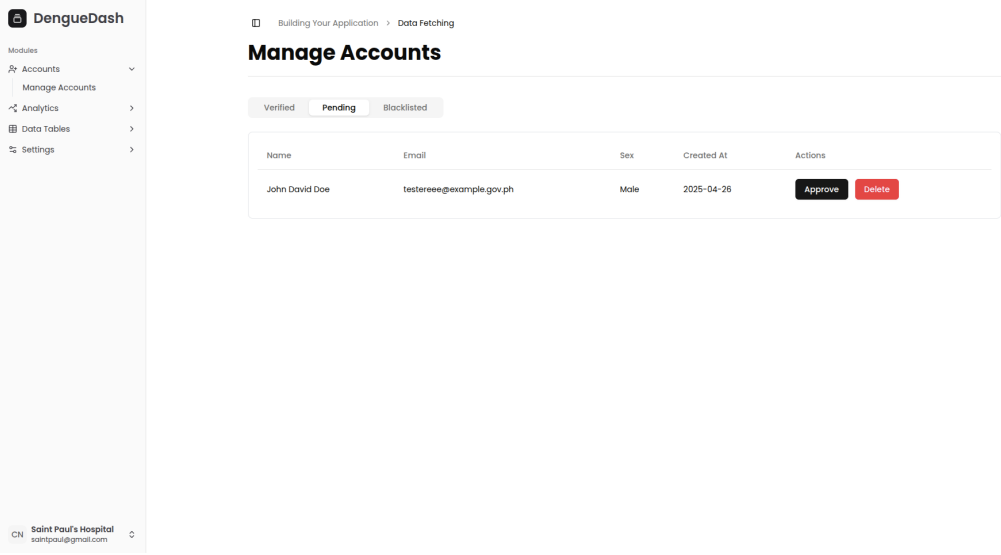

Figure 4.30: List of Pending Accounts

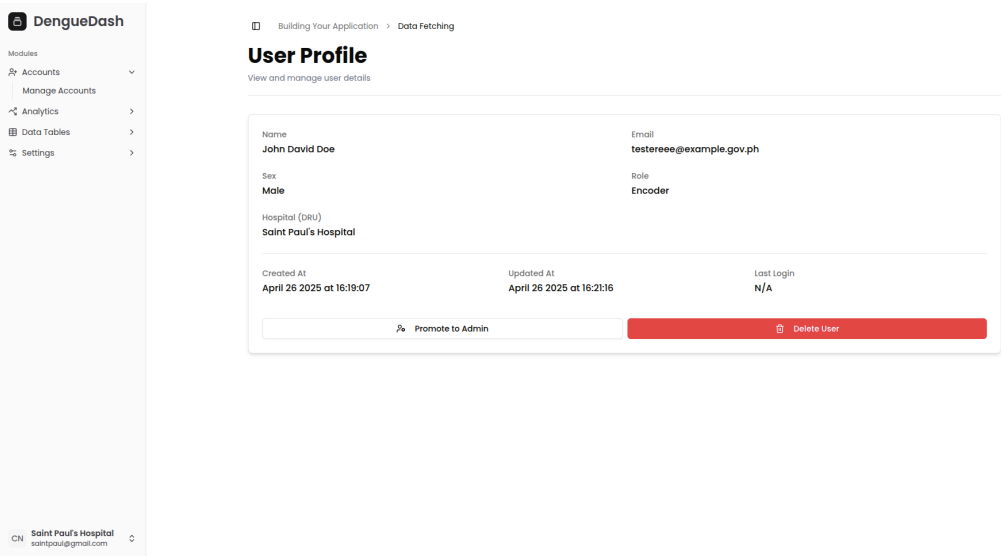

Figure 4.31: Account Details

1038 **Managing DRUs**

1039 Unlike the registration of encoder accounts, the creation of Disease Reporting
1040 Units can only be done within the web application, and the user performing the
1041 creation must be an administrator of a surveillance unit. Figure 4.32 presents the

1042 fields the admin user must fill out, and once completed, the new entry will show
1043 as being managed by that unit, as shown in Figure 4.33. Figure 4.34, on the other
1044 hand, shows the details provided in the registration form as well as its creation
1045 details. There is also an option to delete the DRU, and when invoked, all the
1046 accounts being managed by it, and the cases reported under those accounts will
1047 be soft-deleted.

1048 4.7 User Testing

1049 To evaluate the usability of the system, the System Usability Scale (SUS) was
 1050 utilized. SUS is a Likert-scale-based questionnaire comprising 10 items that are
 1051 critical to assessing system usability. A total of five participants completed the sur-
 1052 vey. Their responses were processed following the step-by-step calculation method
 1053 adopted from (Babich, 2015). The resulting usability scores for each participant
 1054 are shown in Table 4.5.

Participant	Usability Score
1	95.0
2	90.0
3	85.0
4	87.5
5	85.0
Average	88.5

Table 4.5: Computed System Usability Scores per Participant

1055 The average System Usability Scale (SUS) score across systems is typically
 1056 68 (Babich, 2015). In this testing, the system achieved an average SUS score
 1057 of 88.5, indicating a highly positive user experience. This score suggests that
 1058 participants found the system not only enjoyable to use but also intuitive enough

1059 to recommend to others. Furthermore, it demonstrates that the system is suitable
1060 for real-world applications without presenting significant complexity for first-time
1061 users.

1062 4.8 Conclusion

1063 Revolutionizing Dengue Surveillance: The Rise of AI-Driven Forecast- 1064 ing

1065 The development of DengueWatch marks a transformative leap forward in pub-
1066 lic health technology, providing Iloilo City with a centralized system to combat
1067 one of the most persistent mosquito-borne diseases. Previously, data was recorded
1068 manually on paper, making tracking and analysis slow and error-prone. Dengue-
1069 Watch digitizes this process, enabling faster, more accurate monitoring. More
1070 than an academic project, DengueWatch serves as a practical solution aimed at
1071 shifting the approach from reactive outbreak response to proactive prevention. By
1072 combining deep learning models with real-time climate data integration, the sys-
1073 tem achieves a level of accuracy and usability that makes it viable for real-world
1074 deployment.

1075 At the heart of DengueWatch is a Long Short-Term Memory (LSTM) neu-
1076 ral network, which outperformed traditional forecasting models such as ARIMA
1077 and Kalman Filter. The LSTM model achieved a Root Mean Square Error
1078 (RMSE) of 16.30, compared to 39.00 and 38.40 for ARIMA and Kalman, respec-
1079 tively—demonstrating a substantial improvement in predictive capability. This
1080 advantage stems from the LSTM’s ability to capture long-term dependencies and
1081 model nonlinear relationships between environmental factors and disease patterns.

1082 The analysis also revealed that climate indicators, particularly rainfall and
1083 humidity, play a significant role in dengue outbreaks, typically leading to a surge
1084 in cases three to five weeks after anomalies are detected. By incorporating these
1085 lagged effects, DengueWatch achieved an explanatory power of 83% ($R^2 = 0.83$),
1086 offering a game-changing advantage for early intervention and resource allocation.

1087 Usability testing further underscored DengueWatch’s readiness for real-world
1088 deployment. The system achieved an average System Usability Scale (SUS) score
1089 of 88.5, significantly above the industry benchmark of 68. This indicates that
1090 users found the system intuitive, efficient, and suitable for operational use in
1091 public health contexts. Key features such as a user-friendly dashboard, a two-week
1092 forecasting window aligned with mosquito life cycles, and automated outbreak
1093 alerts ensure that the system supports timely, effective responses.

1094 Beyond its immediate application in Iloilo City, the framework behind Dengue-
1095 Watch holds the potential for broader impact. With minor adaptations, it can
1096 be scaled nationally through integration with Department of Health surveillance
1097 systems.

1098 DengueWatch exemplifies how deep learning can bridge the gap between data
1099 science and life-saving interventions. It empowers health workers to act preemp-
1100 tively, policymakers to allocate resources strategically, and communities to en-
1101 gage in early preventive measures. As climate change accelerates the spread of
1102 vector-borne diseases, systems like DengueWatch will become indispensable in
1103 safeguarding public health. This system not only demonstrates the power of AI
1104 in epidemiological forecasting but also lays the foundation for a smarter, more
1105 resilient approach to combating infectious diseases in the years ahead.

1106 **Keywords:** Predictive epidemiology, LSTM neural networks, climate-health
1107 modeling, decision support systems, outbreak early warning
