Abstract

Dengue fever remains a significant public health concern in the Philippines, with cases rising dramatically in recent years. Nationwide outbreaks have placed immense strain on healthcare systems, underscoring the need for innovative approaches to surveillance and response. In Iloilo City, this national trend was reflected in a significant surge, with the Iloilo Provincial Health Office reporting 4,585 cases and 10 fatalities as of August 10, 2023—a 319% increase from the previous year’s 1,095 cases and one death. This research focused on developing a centralized system for monitoring and forecasting dengue trends in Iloilo City, incorporating graphical visualizations such as heatmaps, trends, and historical graphs. The study explored the application of artificial intelligence (AI) in dengue prediction, utilizing deep learning models. The performance of the Long Short-Term Memory (LSTM) model was compared with traditional statistical methods, including non-seasonal and seasonal Autoregressive Integrated Moving Average (ARIMA) models and the Kalman Filter. Evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) were used to identify the most effective model for integration into the system. Forecasting was based on climate variables such as temperature, rainfall, relative humidity, and previous monthly case counts. The LSTM model emerged as the best performer with an RMSE of 16.15, demonstrating its suitability for time-series predictions, while the Kalman Filter showed the poorest performance with an RMSE of 38.40. By integrating predictive analytics with real-time data visualization, the proposed system aims to support public health agencies, such as the Department of Health (DOH), by providing actionable insights for proactive intervention strategies. This AI-driven solution enhances traditional outbreak reporting systems by enabling timely, data-informed decisions to mitigate the impact of dengue in the region.

Keywords: ARIMA, artificial intelligence, dengue prediction, LSTM, Kalman Filter, deep learning, climate variables, public health, outbreak mitigation

Chapter 1

Introduction

1.1 Overview

From 2020 to 2022, dengue cases declined due to reduced surveillance during the COVID-19 pandemic (WHO, 2023), but cases surged in 2023 as restrictions were lifted. This year saw an increase in dengue outbreaks worldwide, with over five million cases and more than 5,000 deaths reported in over 80 countries (Bosano, 2023). Dengue is endemic in the Philippines, leading to longer and more widespread seasonal outbreaks. Globally, dengue infections have increased significantly, posing a major public health challenge. The World Health Organization reported a ten-fold rise in cases between 2000 and 2019, with a peak in 2019 when the disease spread across 129 countries (WHO, 2024).

Iloilo City and Province are intensifying efforts to curb the rising dengue cases (Lena, 2024). As of August 10, 2023, the Iloilo Provincial Health Office recorded 4,585 cases and 10 deaths, a 319% increase from last year's 1,095 cases and one death. Governor Arthur Defensor Jr. confirmed that the province has reached the dengue outbreak threshold based on Department of Health (DOH). Local government units (LGUs) have been informed, and the province's disaster management office is on blue alert, indicating disaster mode. (Perla, 2024)

In Iloilo City, 649 dengue cases were recorded this year 2024, with two deaths. Cases cluster in 40 out of 180 barangays, meaning multiple cases are being reported in these areas over several weeks. The city's health officer, Dr. Roland Jay Fortuna, reported high utilization of non-COVID-19 hospital beds, reaching over 76%, prompting concerns about hospital capacity.

175 This study explores the monitoring and forecasting of dengue outbreaks by an-
176 alyzing key factors such as temperature, relative humidity, and historical dengue
177 cases, using different models. The findings aim to provide an advanced, AI-driven
178 alternative for dengue prevention and control, targeting agencies like the Depart-
179 ment of Health (DOH). By aligning with the national AI Roadmap, particularly
180 in Iloilo City, this research aspires to improve outbreak responses through cutting-
181 edge technology rather than traditional reporting methods.

182 1.2 Problem Statement

183 Dengue remains a critical public health challenge worldwide, with cases increasing
184 due to the easing of COVID-19 restrictions and heightened global mobility. While
185 a temporary decline in cases was observed during the pandemic (2020–2022) due
186 to reduced surveillance efforts, 2023 marked a resurgence, with over five million
187 cases and more than 5,000 deaths reported across 80 countries. In dengue-endemic
188 regions like the Philippines, the threat is particularly severe. In Iloilo City and
189 Province, dengue cases rose by 319% as of August 2023, overwhelming local health-
190 care systems. This surge strained resources, with over 76% of non-COVID-19 hos-
191 pital beds occupied by dengue patients, highlighting the urgent need for effective
192 predictive tools. The lack of a reliable system to monitor and forecast dengue
193 outbreaks contributes to delayed interventions, exacerbating public health risks
194 and healthcare burdens in the region.

195 1.3 Research Objectives

196 1.3.1 General Objective

197 This study aims to develop an AI-based dengue forecasting and monitoring system
198 for Iloilo City and Province. The researchers will train and compare multiple deep
199 learning models to predict dengue case trends based on climate data and historical
200 dengue cases to help public health officials in possible dengue case outbreaks.

201 1.3.2 Specific Objectives

202 Specifically, this study aims to:

- 203 1. Gather dengue data from the Iloilo Provincial Health Office and climate data
204 (including temperature, rainfall, wind, and humidity) from online sources.
205 Combine and aggregate these data into a unified dataset to facilitate com-
206 prehensive dengue case forecasting.
- 207 2. Evaluate deep learning models for predicting dengue cases using metrics
208 such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE),
209 and Mean Squared Error (MSE). Compare the performance of these models
210 to determine the most accurate forecasting approach.
- 211 3. Develop a web-based analytics dashboard that integrates a predictive model
212 and provides data management system for dengue cases in Iloilo City and
213 the Province.
- 214 4. Assess the usability and effectiveness of the analytics dashboard through
215 structured feedback and surveys involving health professionals and policy-
216 makers.

217 1.4 Scope and Limitations of the Research

218 This study aims to gather dengue data from the Iloilo Provincial Health Office
219 and climate data from online sources such as PAGASA or weatherandclimate.com.
220 These data will be preprocessed, cleaned, and combined into a unified dataset to
221 facilitate comprehensive dengue case forecasting. However, the study is limited by
222 the availability and completeness of historical data. Inconsistent or missing data
223 points may introduce biases and reduce the quality of predictions. Furthermore,
224 the granularity of the data will be in a weekly format.

225 To evaluate deep learning models for predicting dengue cases, the study will
226 train and compare the performance of various models, using metrics like Mean
227 Absolute Error (MAE) and Root Mean Square Error (RMSE). While these models
228 aim to provide accurate forecasts, their performance is heavily influenced by the
229 quality and size of the dataset. Limited or low-quality data may lead to suboptimal
230 predictions. Additionally, the models cannot fully account for external factors
231 such as public health interventions or socio-economic conditions which may impact
232 dengue transmission dynamics.

233 The study also involves developing a web-based analytics dashboard that in-
234 tegrates predictive models and provides a data management system for dengue
235 cases in Iloilo City and the Province. This dashboard will offer public health
236 officials an interactive interface to visualize dengue trends, input new data, and

237 identify risk areas. However, its usability depends on feedback from stakeholders,
238 which may vary based on their familiarity with analytics tools. Moreover, exter-
239 nal factors such as limited internet connectivity or device availability in remote
240 areas may affect the system’s adoption and effectiveness. While the dashboard
241 provides valuable insights, it cannot incorporate all factors influencing dengue
242 transmission, emphasizing the need for ongoing validation and refinement.

243 1.5 Significance of the Research

244 This study’s development of an AI-based dengue forecasting and monitoring sys-
245 tem has wide-reaching significance for various stakeholders in Iloilo City:

- 246 • **Public Health Agencies:** Organizations like the Department of Health (DOH)
247 and local health units in Iloilo City and Province stand to benefit greatly
248 from the system. With dengue predictions, we can help these agencies opti-
249 mize their response strategies and implement targeted prevention measures
250 in high-risk areas before cases escalate.
- 251 • **Local Government Units (LGUs):** LGUs can use the system to support
252 their disaster management and health initiatives by proactively addressing
253 dengue outbreaks. The predictive insights allow for more efficient planning
254 and resource deployment in barangays and communities most vulnerable to
255 outbreaks, improving overall public health outcomes.
- 256 • **Healthcare Facilities:** Hospitals and clinics, which currently face high bed
257 occupancy rates during dengue season will benefit from early outbreak fore-
258 casts that can help in managing patient inflow and ensuring adequate hos-
259 pital capacity.
- 260 • **Researchers and Policymakers:** This AI-driven approach contributes valu-
261 able insights for researchers studying infectious disease patterns and policy-
262 makers focused on strengthening the national AI Roadmap. The system’s
263 data can support broader initiatives for sustainable health infrastructure
264 and inform policy decisions on resource allocation for dengue control.
- 265 • **Community Members:** By reducing the frequency and severity of outbreaks,
266 this study ultimately benefits the community at large. This allows for timely

267 awareness campaigns and community engagement initiatives, empowering
268 residents with knowledge and preventative measures to protect themselves
269 and reduce the spread of dengue.

Chapter 2

Review of Related Literature

2.1 Dengue

Dengue disease is a tropical and subtropical mosquito-borne viral illness and is a major health concern in the Philippines (Bravo, Roque, Brett, Dizon, & L’Azou, 2014). The majority of individuals with dengue experience no symptoms. Fever is the most common symptom, typically 4 to 7 days after being bitten by an infected mosquito (Zhou & Malani, 2024). In recent years, the trend of dengue cases in the Philippines has shown notable fluctuations, with periodic outbreaks occurring every 3 to 5 years, often influenced by climatic and environmental changes. According to the Department of Health (DOH), the number of reported cases has steadily increased over the past decades, attributed to urbanization, population growth, and inadequate vector control measures (World Health Organization (WHO), 2018). Moreover, studies suggest that El Niño and La Niña events have significant effects on dengue incidence, with warmer temperatures and increased rainfall providing favorable breeding conditions for mosquitoes (Watts, Burke, Harrison, Whitmire, & Nisalak, 2020). The study of Carvajal et. al. highlights the temporal pattern of dengue cases in Metropolitan Manila and emphasizes the significance of relative humidity as a key meteorological factor, alongside rainfall and temperature, in influencing this pattern (Carvajal et al., 2018).

2.2 Outbreak Definition

The definition of an outbreak is a critical factor in disease surveillance, as it determines the threshold at which an unusual increase in cases is considered a

293 public health concern. Studies suggest that outbreak thresholds should be context-
294 specific, given the variability in transmission dynamics across different locations
295 (Runge-Ranzinger et al., 2016). Outbreak definitions defined using the Endemic
296 Channel often base thresholds on 2 standard deviations (SD) above the mean
297 number of historic dengue cases. Other studies (Hemisphere, 2015) also used an
298 alert threshold of a 5-year mean plus 2 standard deviations. A study by (Brady,
299 Smith, Scott, & Hay, 2015) discussed that definitions of dengue outbreaks differ
300 significantly across regions and time, making them inconsistent and incomparable.

301 From the studies above, this research implements an outbreak definition basing
302 the threshold on 2 standard deviations (SD) above the mean number of historic
303 dengue cases. It is important to note that for future outbreak definitions, addi-
304 tional local context like available hospital space etc., must be taken into account
305 for a more effective outbreak definition.

306 2.3 Existing System: RabDash DC

307 RabDash, developed by the University of the Philippines Mindanao, is a web-
308 based dashboard for rabies data analytics. It combines predictive modeling with
309 genomic data, enabling local health authorities to optimize interventions and al-
310 locate resources more effectively. RabDash’s modules include trend visualization,
311 geographic hotspot mapping, and predictive forecasting, utilizing Long Short-
312 Term Memory (LSTM) models for time-series forecasting (RabDashDC, 2024).

313 For DengueWatch, RabDash serves as a strong inspiration, particularly in
314 its monitoring, historical trend visualization, and forecasting capabilities. These
315 features align well with the needs of dengue control efforts, providing real-time
316 insights into outbreak trends and enabling more effective, data-driven decision-
317 making. RabDash’s architecture is relevant to the DengueDash, as dengue out-
318 breaks similarly require time-series forecasting models. By using LSTM, RabDash
319 effectively models trends in outbreak data, which provides a framework for adapt-
320 ing LSTM to dengue forecasting. Research indicates that LSTM models outper-
321 form traditional methods, such as ARIMA and MLP, in handling the complexities
322 of time-dependent epidemiological data (Ligue & Ligue, 2022).

2.4 Deep Learning

The study of (Ligue & Ligue, 2022) highlights how data-driven models can help predict dengue outbreaks. The authors compared traditional statistical methods, such as non-seasonal and seasonal autoregressive integrated moving average (ARIMA), and traditional feed-forward network approach using a multilayer perceptron (MLP) model with a deep learning approach using the long short-term memory (LSTM) architecture in their prediction model. They found that the LSTM model performs better in terms of accuracy. The LSTM model achieved a much lower root mean square error (RMSE) compared to both MLP and ARIMA models, proving its ability to capture complex patterns in time-series data (Ligue & Ligue, 2022). This superior performance is attributed to LSTM’s capacity to capture complex, time-dependent relationships within the data, such as those between temperature, rainfall, humidity, and mosquito populations, all of which contribute to dengue incidence (Ligue & Ligue, 2022).

2.5 Kalman Filter

The Kalman Filter is another powerful tool for time-series forecasting that can be integrated into our analysis. It provides a recursive solution to estimating the state of a linear dynamic system from a series of noisy measurements. Its application in epidemiological modeling can enhance prediction accuracy by accounting for uncertainties in the data (Li et al., 2022). Studies have shown that Kalman filters are effective in predicting infectious disease outbreaks by refining estimates based on observed data. A study published in *Frontiers in Physics* utilized the Kalman filter to predict COVID-19 deaths in Ceará, Brazil. They found that the Kalman filter effectively tracked the progression of deaths and cases, providing critical insights for public health decision-making (Ahmadini et al., 2021). Another research article in *PLOS ONE* focused on tracking the effective reproduction number (R_t) of COVID-19 using a Kalman filter. This method estimated the growth rate of new infections from noisy data, demonstrating that the Kalman filter could maintain accurate estimates even when case reporting was inconsistent (Arroyo-Marioli, Bullano, Kucinskas, & Rondón-Moreno, 2021).

Our study will compare ARIMA, seasonal ARIMA, Kalman Filter, and LSTM models using our own collected dengue case data along with weather data to identify the most effective model for real-time forecasting.

2.6 Weather Data

The relationship between weather patterns and mosquito-borne diseases is inherently nonlinear, meaning that fluctuations in disease cases do not respond proportionally to changes in climate variables (Colón-González, Fezzi, Lake, & Hunter, 2013). Weather data, such as minimum temperature and accumulated rainfall, are strongly linked to dengue case fluctuations, with effects observed after several weeks due to mosquito breeding and virus incubation cycles. Integrating these lagged weather effects into predictive models can improve early warning systems for dengue control (Cheong, Burkart, Leitão, & Lakes, 2013). A study also suggests that weather-based forecasting models using variables like mean temperature and cumulative rainfall can provide early warnings of dengue outbreaks with high sensitivity and specificity, enabling predictions up to 16 weeks in advance (Hii, Zhu, Ng, Ng, & Rocklöv, 2012).

We will utilize weather data, including variables such as temperature, rainfall, and humidity, as inputs for our dengue forecasting model. Given the strong, nonlinear relationship between climate patterns and dengue incidence, these weather variables, along with their lagged effects, are essential for enhancing prediction accuracy and providing timely early warnings for dengue outbreaks.

2.7 Chapter Summary

This chapter reviewed key literature relevant to our study, focusing on existing systems, predictive modeling techniques and the role of weather data in forecasting dengue outbreaks. We examined systems like RabDash DC, which integrates predictive modeling with real-time data to inform public health decisions, providing a foundational structure for our Dengue Watch System. Additionally, deep learning approaches, particularly Long Short-Term Memory (LSTM) networks, were highlighted for their effectiveness in time-series forecasting, while alternative methods such as ARIMA and Kalman Filters were considered for their ability to model complex temporal patterns and handle noisy data.

The literature further underscores the significance of weather variables—such as temperature and rainfall—in forecasting dengue cases. Studies demonstrate that these variables contribute to accurate outbreak prediction models. Leveraging these insights, our study will incorporate both weather data and historical dengue case counts to build a reliable forecasting model.

Chapter 3

Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

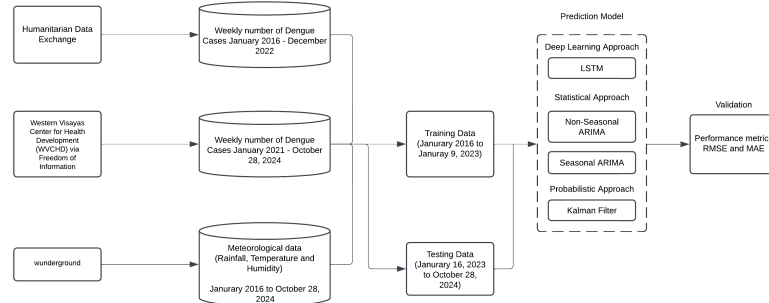

Figure 3.1: Workflow for forecasting the number of weekly dengue cases

This summarizes the workflow for forecasting the number of weekly dengue cases. This workflow focuses on using statistical, deep learning, and probabilistic models to forecast the number of reported dengue cases. The approach involves deploying several models for prediction, including ARIMA and Seasonal ARIMA as statistical approaches, LSTM as a deep learning approach, and the Kalman Filter as a probabilistic approach. These methods are compared with each other to determine the most accurate model.

401 3.1 Research Activities

402 3.1.1 Gather Dengue Data and Climate Data to Create a 403 Complete Dataset for Forecasting

404 Acquisition of Dengue Case Data

405 The historical dengue case dataset used in this study was obtained from the Hu-
406 manitarian Data Exchange and the Western Visayas Center for Health Develop-
407 ment (WVCHD) via Freedom of Information (FOI) requests. The decision to use
408 weekly intervals was driven by the need for precision and timeliness in captur-
409 ing fluctuations in dengue cases and weather conditions. Dengue transmission is
410 influenced by short-term changes in weather variables such as rainfall and temper-
411 ature, which impact mosquito breeding and virus transmission cycles. A weekly
412 granularity allowed the model to better capture these short-term trends, enabling
413 more accurate predictions and responsive public health interventions.

414 Moreover, using a weekly interval provided more data points for training the
415 models compared to a monthly format. This is particularly critical in time series
416 modeling, where larger datasets help improve the robustness of the model and its
417 ability to generalize to new data. Also, the collection of weather data was done
418 by utilizing web scraping techniques to extract weekly weather data (e.g., rainfall,
419 temperature, and humidity) from Weather Underground (wunderground.com).

420 421 Data Fields

- 422 • **Time.** Represents the specific year and week corresponding to each entry
423 in the dataset.
- 424 • **Rainfall.** Denotes the observed average rainfall, measured in millimeters,
425 for a specific week.
- 426 • **Humidity.** Refers to the observed average relative humidity, expressed as
427 a percentage, for a specific week.
- 428 • **Max Temperature.** Represents the observed maximum temperature, mea-
429 sured in degrees Celsius, for a specific week.
- 430 • **Average Temperature.** Represents the observed average temperature,
431 measured in degrees Celsius, for a specific week.

- 432 • **Min Temperature.** Represents the observed minimum temperature, mea-
433 sured in degrees Celsius, for a specific week.
- 434 • **Wind.** Represents the observed wind speed, measured in miles per hour
435 (mph), for a specific week.
- 436 • **Cases.** Refers to the number of reported dengue cases during a specific
437 week.

438 **Data Integration and Preprocessing**

439 The dengue case data was integrated with the weather data to create a com-
440 prehensive dataset, aligning the data based on corresponding timeframes. The
441 dataset underwent a cleaning process to address any missing values, outliers, and
442 inconsistencies to ensure its accuracy and reliability. To ensure that all features
443 and the target variable were on the same scale, a MinMaxScaler was applied to
444 normalize both the input features (climate data) and the target variable (dengue
445 cases).

446 **Exploratory Data Analysis (EDA)**

- 447 • Analyzed trends, seasonality, and correlations between dengue cases and
448 weather factors.
- 449 • Created visualizations like time series plots and scatterplots to highlight
450 relationships and patterns in the data.

451 **Outbreak Detection**

452 To detect outbreaks, we computed the outbreak threshold value of dengue cases
453 using the formula,

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (3.1)$$

454 where μ is the historical mean and σ is the standard deviation.

455 3.1.2 Develop and Evaluate Deep Learning Models for 456 Dengue Case Forecasting

457 The deep learning models were developed and trained to forecast weekly dengue
458 cases using historical weather data (rainfall, temperature, wind, and humidity)
459 and dengue case counts. The dataset was normalized and divided into training and
460 testing sets, ensuring temporal continuity to avoid data leakage. The methodology
461 for preparing and training the model are outlined below.

462 Data Preprocessing

463 The raw dataset included weekly aggregated weather variables (rainfall, tempera-
464 ture, wind, humidity) and dengue case counts. The "Time" column was converted
465 to a datetime format to ensure proper temporal indexing. To standardize the data
466 for training, MinMaxScaler was employed, normalizing the feature values and tar-
467 get variable to a range of 0 to 1. This step ensured that the models could efficiently
468 process the data without being biased by feature scaling differences.

469 LSTM Model

470 The dataset was split into training and test sets to evaluate the model's perfor-
471 mance and generalizability:

- 472 • **Training Set:** 80% of the data (572 sequences) was used for model training,
473 enabling the LSTM to learn underlying patterns in historical dengue case
474 trends and their relationship with weather variables.
- 475 • **Test Set:** The remaining 20% of the data (148 sequences) was reserved for
476 testing

477 To prepare the data for LSTM, a sliding window approach was utilized. Se-
478 quences of weeks of normalized features were constructed as input, while the
479 dengue case count for the subsequent week was set as the target variable. This
480 approach ensured that the model leveraged temporal dependencies in the data for
481 forecasting. To enhance the performance of the LSTM model in predicting dengue
482 cases, Bayesian Optimization was employed using the Keras Tuner library. The
483 tuning process aimed to minimize the validation loss (mean squared error) by
484 adjusting key model hyper-parameters. The search space is summarized below:

485 **LSTM units:**

- 486 • min value: 32
- 487 • max value: 128
- 488 • step: 16
- 489 • sampling: linear

490 **Learning Rate:**

- 491 • min value: 0.0001
- 492 • max value: 0.01
- 493 • step: None
- 494 • sampling: log

495 The tuner was instantiated with:

- 496 • **max trials = 10:** Limiting the search to 10 different configurations
- 497 • **executions per trial = 3:** Running each configuration thrice to reduce
498 variance
- 499 • **validation split = 0.2:** Reserving 20% of the training data for validation

500 The hyperparameter tuning was conducted for three different window sizes of
501 data: 5, 10, and 20. This allows the model to have the optimal hyperparameters
502 used for each window size. Training was conducted over 100 epochs with early
503 stopping to prevent overfitting while maintaining computational efficiency. A
504 batch size of 1 was used, enabling the model to process individual sequences,
505 which is suitable for smaller datasets but results in longer training times. The
506 Adam optimizer, known for its adaptive learning capabilities and stability was
507 employed.

508 To validate the effectiveness of the model, cross-validation was implemented.
509 However, standard k-fold cross-validation randomly shuffles the data, which isn't
510 suitable for time series since the order of observations is important. To address
511 this, a time series-specific cross-validation strategy was used with TimeSeriesS-
512 plit from the scikit-learn library. This method creates multiple train-test splits

513 where each training set expands over time and each test set follows sequentially.
514 This approach preserves the temporal structure of the data while helping reduce
515 overfitting by validating the model across different time segments.

516 After training, predictions on both the training and test datasets were rescaled
517 to their original scale using the inverse transformation of MinMaxScaler. Model
518 performance was evaluated using the mean squared error (MSE), root mean
519 squared error (RMSE) and mean absolute error (MAE).

520 **ARIMA**

521 The ARIMA model was utilized to forecast weekly dengue cases, leveraging histor-
522 ical weather data—including rainfall, maximum temperature, and humidity—as
523 exogenous variables alongside historical dengue case counts as the primary depen-
524 dent variable. The dataset was partitioned into training (80%) and testing (20%)
525 sets while maintaining temporal consistency.

526 To identify the optimal ARIMA configuration, a comprehensive grid search
527 was performed across the following parameter ranges:

- 528 • Autoregressive order (p): 0 to 3
- 529 • Differencing order (d): 0 to 2
- 530 • Moving average order (q): 0 to 3

531 Each combination of (p,d,q) was used to fit an ARIMA model, and perfor-
532 mance was evaluated based on the mean squared error (MSE) between the pre-
533 dicted and actual dengue cases on the test set. The parameter set that achieved
534 the lowest MSE was selected as the final model configuration.

535 Following model selection, the best-fit ARIMA model was retrained on the
536 training set and subsequently used to forecast dengue cases for the test period.
537 The predictions were assigned to the **PredictedCases** column in the test dataset.
538 Model performance was further assessed using key evaluation metrics, including
539 MSE, root mean squared error (RMSE), and mean absolute error (MAE). Visual
540 comparisons between actual and predicted dengue cases were produced through
541 line plots to better illustrate the model’s forecasting accuracy.

542 Seasonal ARIMA (SARIMA)

543 The SARIMA modeling process began with data preprocessing, which included
544 handling missing values through interpolation or imputation, and standardizing
545 features to ensure stable model training. The dataset was then split into training
546 and testing sets in an 80:20 ratio, preserving the temporal order of observations.
547 Seasonality analysis was conducted using time series decomposition and autocor-
548 relation plots, which revealed a periodicity of 52 weeks—justifying the adoption
549 of a seasonal model. To fine-tune the model, a grid search was performed over a
550 range of SARIMA parameters $(p,d,q)(P,D,Q)[S]$, while stationarity was validated
551 using the Augmented Dickey-Fuller (ADF) test. The model was then trained
552 on the dataset using rainfall, temperature, and humidity as exogenous variables,
553 with convergence ensured by setting a maximum number of iterations. Residual
554 diagnostics were used to confirm that residuals were uncorrelated, indicating a
555 good model fit. For evaluation, forecasts were compared against actual values,
556 and results were visualized with line plots. Finally, to validate the model’s gener-
557 alizability across different time periods, Time Series Cross-Validation with three
558 folds was applied. This allowed assessment of the model’s performance on multi-
559 ple time segments, providing insights into its robustness in real-world forecasting
560 scenarios.

561 Kalman Filter:

- 562 • Input Variables: The target variable (Cases) was modeled using three re-
563 gressors: rainfall, max temperature, and humidity.
- 564 • Training and Testing Split: The dataset was split into 80% training and
565 20% testing to evaluate model performance.
- 566 • Observation Matrix: The Kalman Filter requires an observation matrix,
567 which was constructed by adding an intercept (column of ones) to the re-
568 gressors.

569 The Kalman Filter’s Expectation-Maximization (EM) method was employed
570 for training, iteratively estimating model parameters over 10 iterations. After
571 training, the smoothing method was used to compute the refined state estimates
572 across the training data. Observation matrices for the test data were constructed
573 in the same manner as for the training set, ensuring compatibility with the learned
574 model parameters. On the test data, the Kalman Filter applied these parameters
575 to predict and correct the estimated dengue cases, providing more stable and
576 accurate forecasts compared to direct regression models. Additionally, a hybrid

577 Kalman Filter–LSTM (KF-LSTM) model was developed to combine the strengths
578 of both approaches. In this setup, the LSTM model was first used to predict
579 dengue cases based on historical data and weather features. The Kalman Filter
580 was then applied as a post-processing step to the LSTM predictions, smoothing
581 out noise and correcting potential errors.

582 **3.1.3 Integrate the Predictive Model into a Web-Based** 583 **Data Analytics Dashboard**

584 **Dashboard Design and Development**

- 585 • Design an intuitive, user-friendly web-based dashboard incorporating:
 - 586 – Interactive visualizations of yearly dengue case trends.
 - 587 – Data input and update forms for dengue and weather data.
 - 588 – Map display of dengue cases in each district in Iloilo City

589 **Model Integration and Deployment**

- 590 • Deploy the best-performing model within the dashboard as a backend service
591 to enable real-time or periodic forecasting.

592 **3.1.4 System Development Framework**

593 The Agile Model is the birthchild of both iterative and incremental approaches
594 in Software Engineering. It aims to be flexible and effective at the same time by
595 being adaptable to change. It's also important to note that small teams looking
596 to construct and develop projects quickly can benefit from this kind of method-
597 ology. As the Agile Method focuses on continuous testing, quality assurance is a
598 guarantee since bugs and errors are quickly identified and patched.

599 **Design and Development**

600 After brainstorming and researching the most appropriate type of application to
601 accommodate both the prospected users and the proposed solutions, the team
602 has decided to proceed with a web application. Given the time constraints and
603 available resources, it has been decided that the said means is the most pragmatic

604 and practical move. The next step is to select modern and stable frameworks
 605 that align with the fundamental ideas learned by the researchers in the university.
 606 The template obtained from WVCHD and Iloilo Provincial Epidemiology and
 607 Surveillance Unit was meticulously analyzed to create use cases and develop a
 608 preliminary well-structured database that adheres to the requirements needed
 609 to produce a quality application. The said use cases serve as the basis of general
 610 features. Part by part, these are converted into code, and with the help of selected
 611 libraries and packages, it resulted in the desired outcome that may still modified
 612 and extended to achieve scalability.

613 Testing and Integration

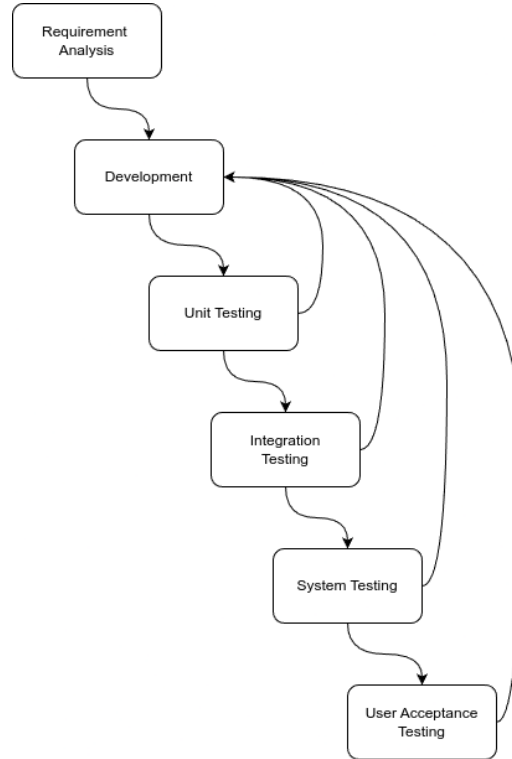

Figure 3.2: Testing Process for DengueWatch

614 Implementing testing is important to validate the system's performance and ef-
 615 ficacy. Thus a series of tests were conducted to identify and resolve bugs during
 616 the developmental phase. Each feature was rigorously tested to ensure quality as-
 617 surance, with particular emphasis on prerequisite features, as development cannot
 618 progress properly if these fail. Because of this, integration between each feature

619 serves as a pillar for a cohesive user experience. Since dengue reports include
620 confidential information, anonymized historical dengue reports were used to train
621 the model and create the foundational architecture of the system. By using func-
622 tional tests, data validation and visualization can be ensured for further continual
623 improvements. Security testing is also important as it is needed to safeguard
624 confidential information when the system is deployed. It includes proper authen-
625 tication, permission views, and mitigating common injection attacks. Finally, a
626 user acceptance test from the prospected users, in this case, doctors, nurses, and
627 other health workers is crucial to assess its performance and user experience. It
628 enables the developers to confirm if the system meets the needs of the problem.

629 **3.2 Development Tools**

630 **3.2.1 Software**

631 **Github**

632 GitHub is a cloud-based platform that tracks file changes using Git, an open-
633 source version control system (*About GitHub and Git - GitHub Docs*, n.d.). It is
634 used in the project to store the application’s source code, manage the system’s
635 source version control, and serve as a repository for the Latex files used in the
636 actual research.

637 **Visual Studio Code**

638 Visual Studio Code is a free, lightweight, and cross-platform source code editor
639 developed by Microsoft (*Why Visual Studio Code?*, 2021). As VS Code supports
640 this project’s programming and scripting languages, it was chosen as the primary
641 source code editor.

642 **Django**

643 Django is a free and open-sourced Python-based web framework that offers an
644 abstraction to develop and maintain a secure web application. As this research
645 aims to create a well-developed and maintainable application, it is in the best
646 interest to follow an architectural pattern that developers and contributors in the

647 future can understand. Since Django adheres to Model-View-Template (MVT)
648 that promotes a clean codebase by separating data models, business logic, and
649 presentation layers, it became the primary candidate for the application’s back-
650 bone.

651 **Next.js**

652 A report by Statista (2024) claims that React is the most popular front-end frame-
653 work among web developers. However, React has limitations that can be a nui-
654 sance in rapid software development, which includes routing and performance op-
655 timizations. This is where Next.js comes in—a framework built on top of React.
656 It offers solutions for React’s deficiency, making it a rising star in the framework
657 race.

658 **Postman**

659 As the application heavily relies on the Application Programming Interface (API)
660 being thrown by the backend, it is a must to use a development tool that facilitates
661 the development and testing of the API. Postman is a freemium API platform
662 that offers a user-friendly interface to create and manage API requests (*What is*
663 *Postman? Postman API Platform*, n.d.).

664 **3.2.2 Hardware**

665 The web application was developed on laptop computers with minimum specifica-
666 tions of an 11th-generation Intel i5 CPU and 16 gigabytes of RAM. Furthermore,
667 an RTX 3060 mobile GPU was also utilized to retrain the integrated model locally.

668 **3.2.3 Packages**

669 **Django REST Framework**

670 Django Rest Framework (DRF) is a third-party package for Django that provides a
671 comprehensive suite of features to simplify the development of robust and scalable
672 Web APIs (Christie, n.d.). These services include Serialization, Authentication
673 and Permissions, Viewsets and Routers, and a browsable API .

674 Leaflet

675 One of the features of the web application is the ability to map the number
676 of cases using a Choropleth Map. Leaflet is the only free, open-sourced, and
677 most importantly, stable JavaScript package that can do the job. With its ultra-
678 lightweight size, it offers a comprehensive set of features that does not trade
679 off performance and usability (*Leaflet — an open-source JavaScript library for*
680 *interactive maps*, n.d.).

681 Chart.js

682 Another feature of the application is to provide users with informative, approach-
683 able data storytelling that is easy for everyone to understand. The transformation
684 of pure data points and statistics into figures such as charts is a big factor. Thus,
685 there is a need for a package that can handle this feature without compromising
686 the performance of the application. Chart.js is a free and open-source JavaScript
687 package that is made to meet this criteria as it supports various types of charts
688 (*Chart.js*, n.d.).

689 Tailwind CSS

690 Using plain CSS in production-quality applications can be counterproductive.
691 Therefore, CSS frameworks were developed to promote consistency and accelerate
692 the rapid development of web applications (Joel, 2021). One of these is Tailwind,
693 which offers low-level utility classes that can be applied directly to each HTML
694 element to create a custom design (*Tailwind CSS - Rapidly build modern web-*
695 *sites without ever leaving your HTML.*, n.d.). Given the limited timeline for this
696 project, using this framework is a wise choice due to its stability and popularity
697 among developers.

698 Shadcn

699 Shadcn offers a collection of open-source UI boilerplate components that can be
700 directly copied and pasted into one's project. With the flexibility of the provided
701 components, Shadcn allows developers to have full control over customization and
702 styling. Since this is built on top of Tailwind CSS and Radix UI, it is supported
703 by most modern frontend frameworks, including Next.js (Shadcn, n.d.).

704 **Zod**

705 Data validation is integral in this web application since it will handle crucial data
706 that will be used for analytical inferences and observations. Since Zod is primarily
707 used for validating and parsing data, it ensures proper communication between
708 the client and the server (Zod, n.d.).

709 3.3 Application Requirements

710 3.3.1 Backend Requirements

711 Database Structure Design

712 Determining how data flows and how it would be structured is crucial in creating
713 the system as it defines how extendible and flexible it would be for future features
714 and updates. Thus, creating a comprehensive map of data ensures proper nor-
715 malization that eliminates data redundancy and improves data integrity. Figure
716 3.3 depicts the designed database schema that showcases the relationship between
717 the application's entities.

Figure 3.3: Entity-Relationship Database Schema Hybrid Diagram for DengueDash Database Structure

718 3.3.2 User Interface Requirements

719 Admin Interface

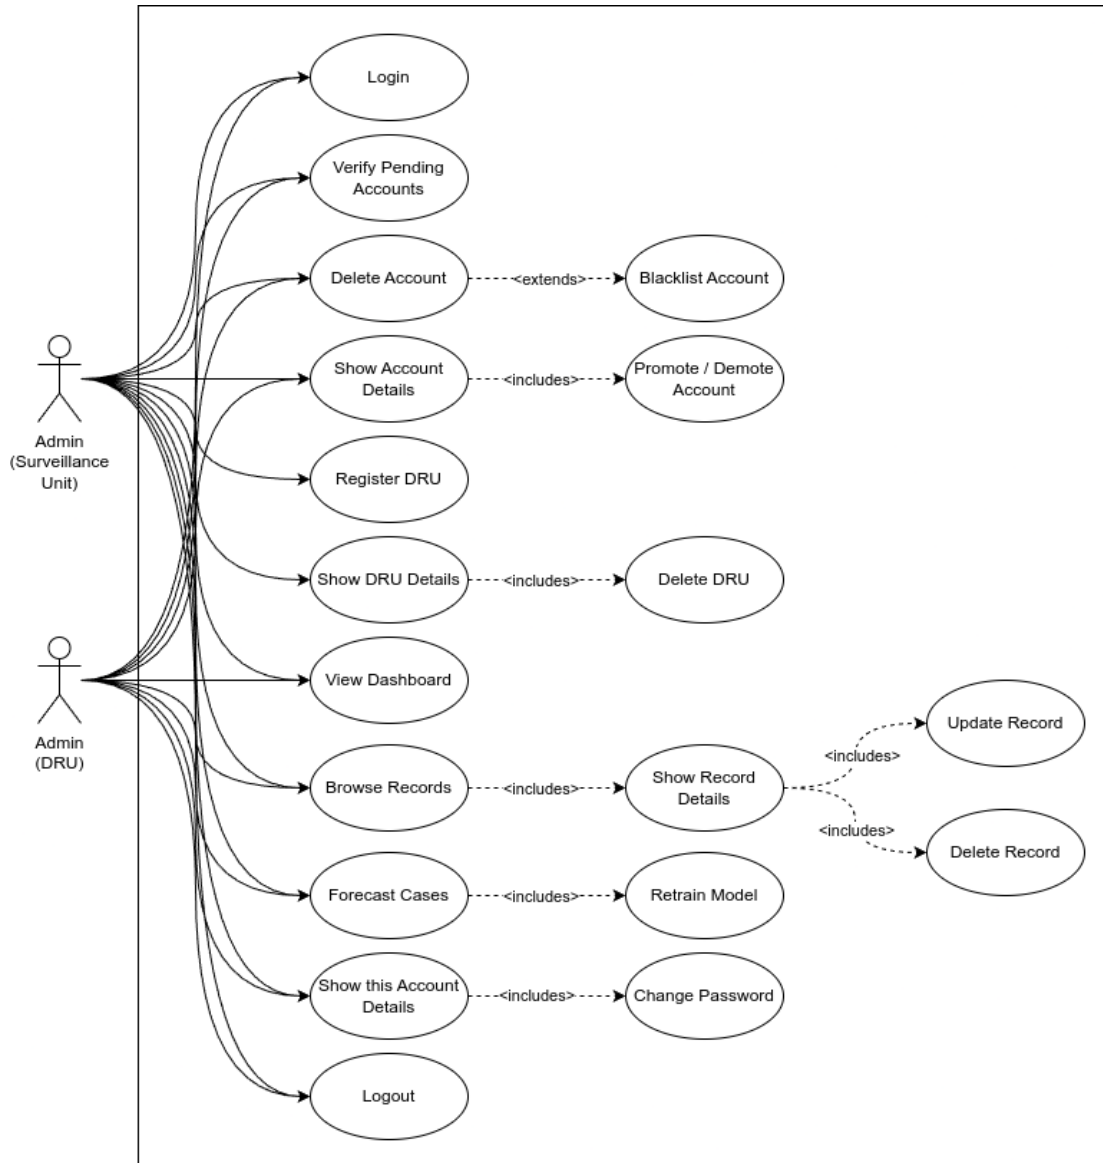

Figure 3.4: Use Case Diagram for Admins

720 Figure 3.4 shows the actions of an admin for a specific Disease Reporting Unit
 721 (DRU) and an admin for a specific Surveillance Unit can take in the application.
 722 Both of them include the management of accounts, browsing records, and fore-
 723 casting and retraining all the consolidated data under their supervision. Most

724 importantly, these users must verify the encoders who register under their ju-
 725 risdiction before allowing their account to access the application in the name of
 726 safeguarding the integrity of the data. The only advantage of the latter type of ad-
 727 ministrator is that it has a one-step higher authorization as it manages the DRUs.
 728 In addition, only the authorized surveillance unit administrator can register and
 729 create a DRU to uphold transparency and accountability.

730 Encoder Interface

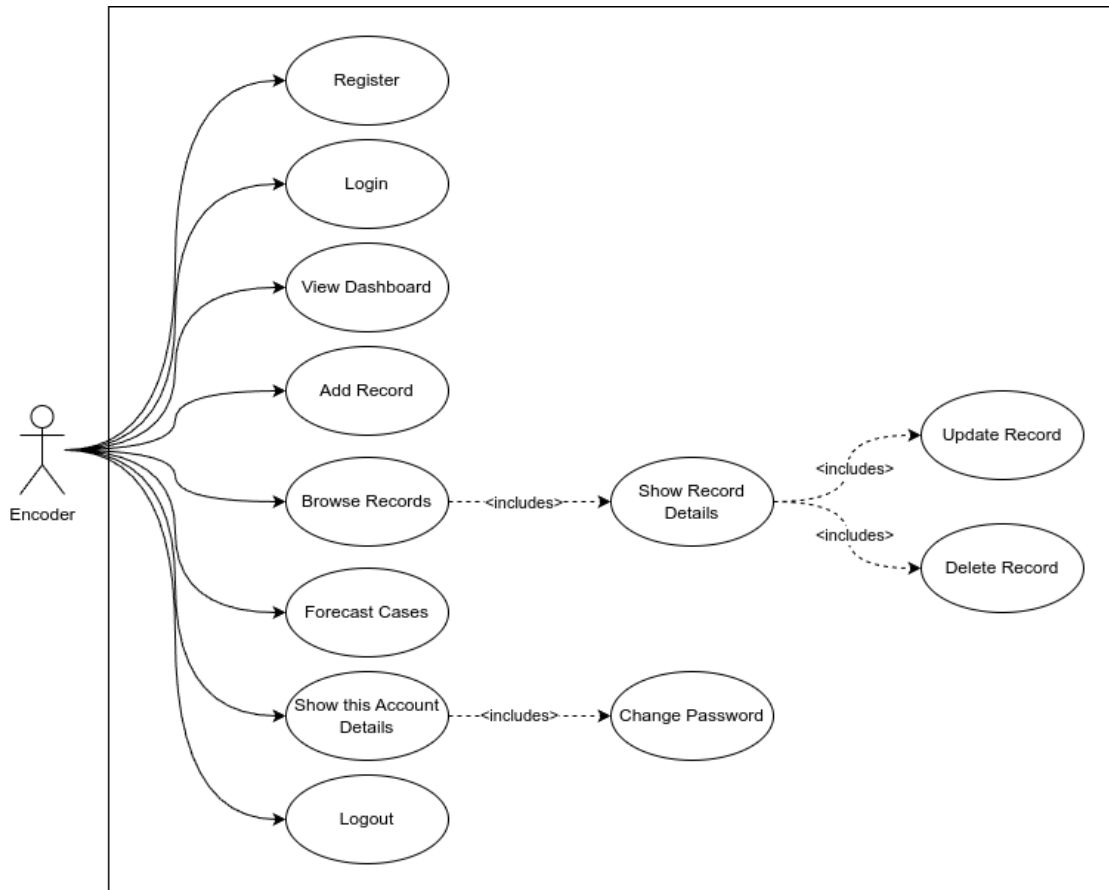

Figure 3.5: Use Case Diagram for Encoder

731 Figure 3.5, on the other hand, illustrates the use cases for the system's primary
 732 users. These users can register but must wait for further verification to access the
 733 application. Similar to the previous interfaces, encoders can browse and manage
 734 records, as well as forecast the consolidated cases under a specific surveillance or
 735 disease reporting unit, but they are not allowed to retrain the model. Lastly, they

736 are the only type of user that can file and create dengue cases by filling out a form
737 with the required details.

738 **3.3.3 Security and Validation Requirements**

739 **Password Encryption**

740 Storing passwords as plain text in the database is a disgrace and a mortal sin in
741 production. It is important to implement precautionary methods such as hashing
742 and salting, followed by encryption with a strong algorithm, to prevent bad actors
743 from using the accounts for malicious transactions. By default, Django generates
744 a unique random salt for each password and encrypts it with Password-Based Key
745 Derivation Function 2 (PBKDF2) with a SHA256 hash function. Utilizing these
746 techniques ensures that in the event of a data breach, cracking these passwords
747 would be time-consuming and useless for the attackers.

748 **Authentication**

749 DengueWatch utilizes JSON Web Tokens (JWT) to authenticate the user. Since
750 the mechanism operates in a stateless manner, tokens are served only after a
751 successful login, eliminating the need for the server to keep a record of the token,
752 which is vulnerable to session hijacking. In addition, these tokens are signed with
753 a secret key, ensuring they have not been tampered with.

754 **Data Validation**

755 Both the backend and frontend should validate the input from the user to preserve
756 data integrity. Thus, Zod is implemented in the latter to help catch invalid inputs
757 from the user. By doing this, the user can only send proper requests to the server
758 which streamlines the total workflow. On the other hand, Django has also a built-
759 in validator that checks the data type and ensures that the input matches the
760 expected format on the server side. These validation processes ensure that only
761 valid and properly formatted data is accepted, which reduces the risk of errors
762 and ensures consistency across the web application.

3.4 Calendar of Activities

A Gantt chart showing the schedule of the activities is included below. Each bullet represents approximately one week of activity.

Table 3.1: Timetable of Activities for 2024

Activities	Aug	Sept	Oct	Nov	Dec
Project Initiation and Team Formation	••

Integrate the Best Model to the System	•	••••			
Extend Features to Accommodate a National Setting		•	••		
User Testing			••	•	
Documentation	••	••••	••••	••••	••••

Chapter 4

Results and Discussion/System Prototype

4.1 Data Gathering

The data for dengue case prediction was gathered from a variety of reliable sources, enabling a comprehensive dataset spanning from January 2011 to October 2024. This dataset includes 720 rows of data, each containing weekly records of dengue cases along with corresponding meteorological variables, such as rainfall, temperature, and humidity.

1. Dengue Case Data: The primary source of historical dengue cases came from the Humanitarian Data Exchange and the Western Visayas Center for Health Development (WVCHD). The dataset, accessed through Freedom of Information (FOI) requests, provided robust case numbers for the Western Visayas region. The systematic collection of these data points was essential for establishing a reliable baseline for model training and evaluation.
2. Weather Data: Weekly weather data was obtained by web scraping from Weather Underground, allowing access to rainfall, temperature, wind, and humidity levels that correlate with dengue prevalence.

```

784 4.2 Exploratory Data Analysis

785 From the summary above, the dataset consists of 720 weekly records with 8
786 columns:

- 787 • **Time.** Weekly timestamps (e.g. "2011-w1")
- 788 • **Rainfall.** Weekly average rainfall (mm)
- 789 • **MaxTemperature, AverageTemperature, MinTemperature.** Weekly
790 temperature data (C)
- 791 • **Wind.** Wind speed (m/s)
- 792 • **Humidity.** Weekly average humidity (%)
- 793 • **Cases.** Reported dengue cases

	Time	Rainfall	MaxTemperature	AverageTemperature	MinTemperature	Wind	Humidity	Cases

Figure 4.3: Dataset Statistics

From the statistics in figure 4.3, the number of cases ranges from 0 to 319. The average number of dengue cases per week is 23.74, with a median of 12 cases and a standard deviation of 37.14. The distribution is highly skewed, with some weeks experiencing significant number of cases (up to 319 cases). Rainfall shows a wide variation (0 to 445mm), while temperature remains relatively stable, with an average of 28.1 degree celsius. Humidity levels ranges from 73% to 89% with a mean of 81.6%.

Figure 4.4: Distribution of Dengue Cases

In figure 4.4, a histogram of dengue cases shows a right-skewed distribution, indicating that most weeks experience low case counts, while a few weeks record outbreaks.

To further analyze the distribution, dengue cases were categorized into different intervals (Figure 4.5): 0-5 cases, 6-15 cases, 16-30 cases, 31-100 cases and 101+

806 cases. The majority of weeks falls within the 0-5 cases and 6-15 cases categories,
 807 indicating that most weeks have low dengue cases. Meanwhile, weeks with 101+
 cases are rare, suggesting that extreme outbreaks are not frequent.

Figure 4.5: Frequency of Dengue Cases in Different Intervals

808

809 Figure 4.6 illustrates the trend of weekly dengue cases over time. The data
 810 reveals periodic spikes in the number of cases, suggesting a seasonal pattern in
 811 dengue cases. Notably, peak cases are observed during certain periods approx-
 812 imately 3 years, potentially aligning with specific climatic conditions such as
 813 increased rainfall or temperature changes. This underscores the importance of
 814 incorporating climate variables into the forecasting model.

815 Figure 4.7 shows the ranking of correlation coefficients between dengue cases
 816 and selected features, including rainfall, humidity, maximum temperature, aver-
 817 age temperature, minimum temperature, and wind speed. Among these, rainfall
 818 exhibits the highest positive correlation with dengue cases (correlation coefficient
 819 0.13), indicating that increased rainfall may contribute to higher cases counts.
 820 This aligns with existing studies suggesting that stagnant water from heavy rain-
 821 fall creates breeding grounds for mosquitos. It is followed by humidity (0.10),
 822 suggesting that higher humidity levels may enhance mosquito reproduction, lead-
 823 ing to more dengue cases. Temperature has a weak to moderate positive corre-
 824 lation with dengue cases, with maximum temperature (0.09) showing a stronger
 825 relationship than average and minimum temperature.

826 Figure 4.8 shows the ranking of correlation coefficients between dengue cases
 827 and selected features, with the addition of lagged effects. The analysis reveals no

Figure 4.6: Trend of Dengue Cases

Figure 4.7: Ranking of Correlations

improvement in correlation when lagged variables are compared to direct observations. This suggests that the observed values of rainfall, humidity, and maximum temperature remain the most significant predictors for dengue case forecasting. Overall, the exploratory data analysis highlights the significance of rainfall, humidity, and max temperature variables in dengue case forecasting.

Figure 4.8: Ranking of Correlations (with lagged effects)

833 4.3 Outbreak Detection

834 To identify outbreaks, we calculated the outbreak threshold value using the histor-
835 ical mean as the endemic channel. The threshold is determined using the formula:

$$\text{Outbreak Threshold Value} = \mu + 2\sigma \quad (4.1)$$

$$= 23.744444 + 2(37.144813) \quad (4.2)$$

$$= 23.744444 + 74.289626 \quad (4.3)$$

$$= 98.03407 \quad (4.4)$$

836 where μ is the historical mean and σ is the standard deviation.

837 This result indicates that dengue cases exceeding 98 in Iloilo City can be
838 considered an outbreak. However, it is important to note that this threshold
839 serves only as a baseline. Additional parameters, such as the number of hospital
840 beds available in the city, must be considered to compute a more effective threshold
841 and develop an appropriate response strategy.

842 4.4 Model Training Results

843 The models were evaluated using three metrics: MSE, RMSE, and MAE. The
 844 table below provides a summary and comparative analysis of each model's results
 845 across these metrics, offering insights into the strengths and limitations of each
 846 forecasting technique for dengue case prediction in Iloilo City. The lower values
 847 of the three metrics indicate better forecasting performance. Table 4.1 shows that
 848 the models performed differently on testing data. LSTM outperformed the other
 849 models with the lowest RMSE, MSE, and MAE while the other three models had
 850 relatively higher values for the three metrics.

Method	LSTM	Seasonal ARIMA	ARIMA	Kalman Filter	KF-LSTM
Testing MSE	285.54	1261.20	1521.48	1474.82	785.35
Testing RMSE	16.90	34.45	39.00	38.40	25.56
Testing MAE	9.45	18.73	25.80	22.33	14.55
Best Parameters	Window Size: 5 Learning Rate: 0.01 Units: 64	(2,0,2)(0,1,1)	(1,2,2)	Observation Covariance: 10.0 Transition Covariance: $0.1 \times \text{Identity}$	Same as LSTM

Table 4.1: Comparison of different models for dengue prediction

851 4.4.1 LSTM Model

852 The LSTM model was tuned for the following parameters: learning rate and units.
 853 The hyperparameter tuning was conducted for each window size, finding the best
 854 parameters for each window size. Further evaluating which window size is most
 855 suitable for the prediction model, Table 4.2 shows the evaluation metrics for each
 window size used in the LSTM model training.

Window Size	MSE	RMSE	MAE	R ²
5	285.54	16.90	9.45	0.83
10	334.63	18.29	9.85	0.80
20	294.85	17.17	9.35	0.83

Table 4.2: Comparison of Window Sizes

856

857 The results indicate that a window size of 5 weeks provides the most accurate
 858 predictions, as evidenced by the lowest MSE and RMSE values. Furthermore, the
 859 R² score of 0.83 indicates that 83% of the variability in the target variable (cases)
 860 is explained by the independent variables (the inputs) in the model, making it a
 861 reliable configuration overall.

862 Figure 4.9 illustrates the model's performance in predicting dengue cases for
 863 each fold using a window size of 5. As shown in the plot, the training set progres-

864 sively increases with each fold, mimicking a real-world scenario where more data
865 becomes available over time for dengue prediction. Figure 4.10 demonstrates that
866 the predicted cases closely follow the trend of the actual cases, indicating that the
867 LSTM model successfully captures the underlying patterns in the data. It is also
868 evident that as the fold number increases and the training set grows, the accuracy
869 of the predictions on the test set improves. Despite the test data being unseen,
870 the model exhibits a strong ability to generalize, suggesting it effectively leverages
871 past observations to predict future trends.

Figure 4.9: Training Folds - Window Size 5

Figure 4.10: Testing Folds - Window Size 5

872 4.4.2 ARIMA Model

Figure 4.11: ARIMA Prediction Results for Test Set

873 The ARIMA model was developed to capture non-seasonal trends in the data.
 874 To determine the best model configuration, grid search was used to explore vari-
 875 ous combinations of ARIMA parameters, ultimately selecting **ARIMA(1, 2, 2)**.
 876 The model was iteratively refined over **400 iterations** to ensure convergence to
 877 an optimal solution. Figure 4.11 illustrates the comparison between actual and
 878 predicted dengue cases in the test set. As shown in the plot, the ARIMA model
 879 struggled to capture the non-linear characteristics and abrupt spikes in the data.
 880 Consequently, it failed to accurately reflect the fluctuations and outbreak patterns
 881 seen in the actual case counts.

882 The model's performance was assessed using regression metrics to evaluate its
 883 forecasting capability. The ARIMA model yielded the following error metrics:

- 884 • **MSE (Mean Squared Error):** 1521.48
- 885 • **RMSE (Root Mean Squared Error):** 39.01
- 886 • **MAE (Mean Absolute Error):** 25.80

4.4.3 Seasonal ARIMA (SARIMA) Model

To address the limitations of the ARIMA model, a Seasonal ARIMA (SARIMA) model was developed to capture both non-seasonal and seasonal variations in the data.

Figure 4.12: Seasonal ARIMA Prediction Results for Test Set

This model incorporates seasonal parameters, which were tuned using grid search to find the best configuration: **SARIMA(2, 0, 2)(0, 1, 1)[52]**. As with ARIMA, **400 iterations** were applied to ensure a robust fit. As shown in Figure 4.12, the SARIMA model demonstrates a notable improvement in performance. Unlike its non-seasonal counterpart, it effectively captures the general trend and aligns more closely with the peaks observed in the actual dengue cases, indicating its ability to model seasonal dynamics.

The model's performance was assessed using regression metrics to evaluate its forecasting capability. The SARIMA model yielded the following error metrics:

- **MSE:** 1109.69
- **RMSE:** 33.31

902

- **MAE: 18.09**

903

904

905

906

The lower error values, when compared to the ARIMA model, highlight the SARIMA model's superior capability in forecasting dengue cases. Its effectiveness in capturing seasonal patterns contributed to a more accurate representation of the actual cases.

907

908

909

910

911

912

After training the model, the SARIMA model was validated using the same Time Series Cross-Validation strategy employed in the LSTM model. Table 4.3 presents the performance metrics for each fold, as well as the average metrics across all folds. The average RMSE and MAE values were close to those obtained during the initial training phase, indicating that the SARIMA model performed consistently across different time segments.

Fold	MSE	RMSE	MAE
1	659.68	25.68	16.00
2	2127.49	46.12	21.30
3	996.43	31.56	18.89
Average	1261.20	34.45	18.73

Table 4.3: Comparison of SARIMA performance for each fold

913

4.4.4 Kalman Filter Model

914

915

916

917

918

919

920

921

Figure 4.13 shows the comparison between the actual dengue cases and the predicted values on the test set. As illustrated in the plot, the Kalman Filter model demonstrates a moderate ability to follow the general trend of the actual data. While it effectively captures some rising and falling patterns, it still struggles to accurately replicate the sharp peaks and extreme values found in the real case counts. This limitation is particularly noticeable during the large spikes in 2022 and 2024. The model's performance was evaluated using standard regression metrics. The results are as follows:

$$\text{MSE} = 1474.82, \quad \text{RMSE} = 38.40, \quad \text{MAE} = 22.34$$

Figure 4.13: Kalman Filter Prediction Results for Test Set

922 The Kalman Filter was then combined with the LSTM model in order to see
 923 improvements in its predictions. Table 4.4 shows the metrics across three folds
 924 using the same Time Series Cross Validation Strategy employed in the previous
 925 models to see how it performed on different time segments.

Fold	MSE	RMSE	MAE
1	113.59	10.66	6.42
2	752.51	27.43	12.11
3	1489.95	38.60	25.13
Average	785.35	25.56	14.55

Table 4.4: Comparison of KF-LSTM performance for each fold

926 As can be seen in the table above, the performance of the hybrid model demon-
 927 strated improvements in all metrics as compared to just using the Kalman Filter
 928 alone.

4.5 Model Simulation

To evaluate the LSTM model's real-world forecasting ability, a simulation was conducted to predict dengue cases for the year 2025. The model was trained exclusively on data from 2011 to 2024, using both dengue cases and weather variables. Importantly, the actual dengue case values for 2025 were never included during training. Instead, only the weather variables collected for 2025 were input into the model to generate predictions for that year. After prediction, the forecasted dengue cases for 2025 were compared against the true observed cases to assess the model's accuracy. Figure 4.14 shows that the predicted values closely follow the trend, although it may overestimate the dengue cases in some weeks.

Figure 4.14: Predicted vs Actual Dengue Cases 2025

4.6 System Prototype

4.6.1 Home Page

The Home Page is intended for all visitors of the web application. The Analytics Dashboard, which displays relevant statistics for dengue cases at a certain year and location, is the primary component highlighted, as seen in Figure 4.15. This component includes a combo chart that graphs the number of dengue cases and deaths per week in a specific year, a choropleth map that tracks the number of

946 dengue cases per location, and various bar charts that indicate the top locations
947 affected by dengue.

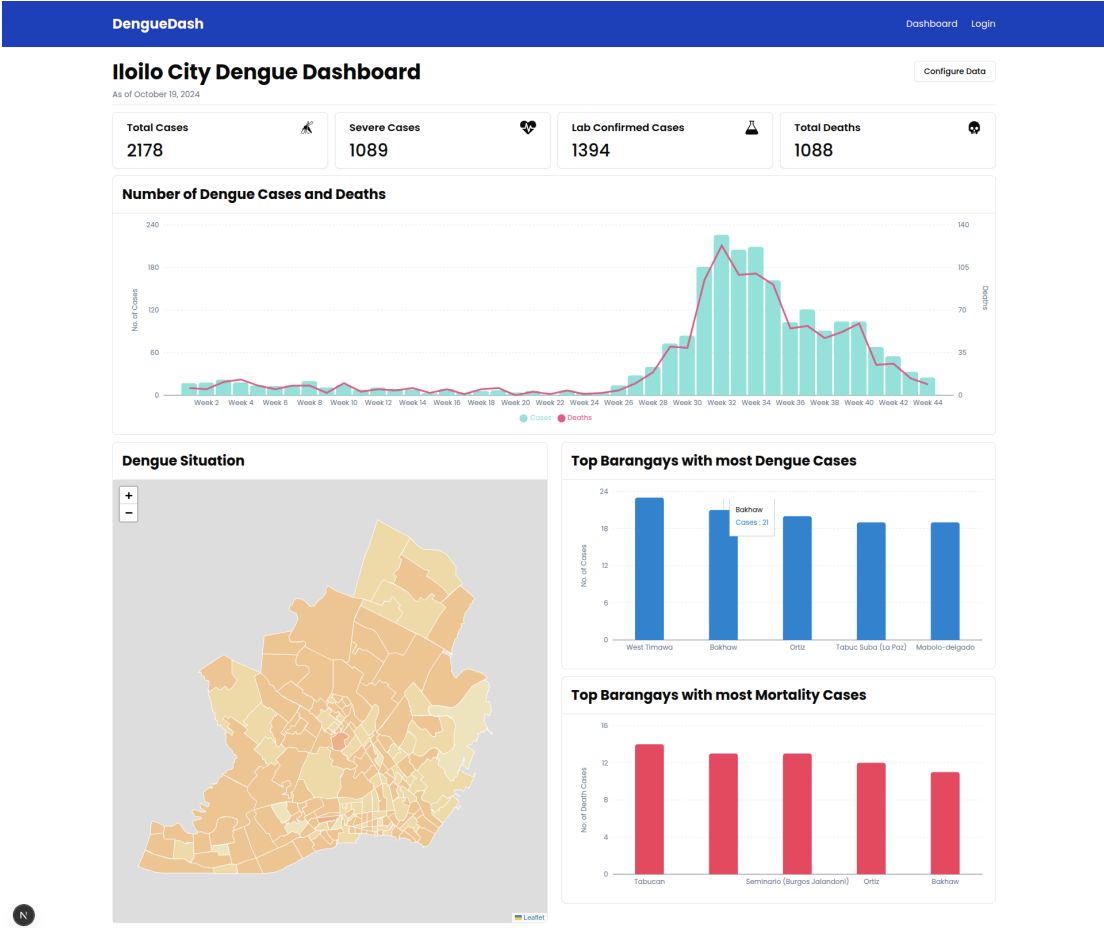

Figure 4.15: Home Page

948 **4.6.2 User Registration, Login, and Authentication**

949 The registration page, as shown in Figure 4.16, serves as a gateway to access the
950 authenticated pages of the web application. Only prospected encoders can create
951 an account since administrator accounts are only made by existing administra-
952 tor accounts to protect the data's integrity in production. After registering, the
953 "encoder account" cannot access the authorized pages yet as it needs to be veri-
954 fied first by an administrator managing the unit the user entered. Once verified,
955 the user can log in to the system through the page shown in Figure 4.17. Af-
956 ter entering the correct credentials, which consist of an email and password, the

957 system uses HTTP-only cookies containing JSON Web Tokens (JWT) to prevent
958 vulnerability to Cross-site Scripting (XSS) attacks. It will then proceed to the
959 appropriate page the type of user belongs to.

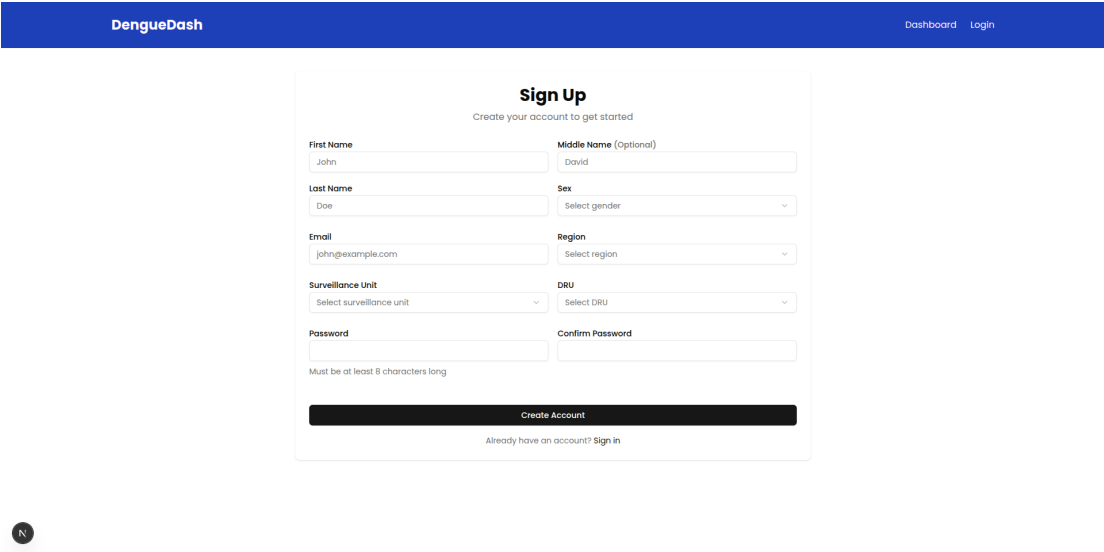

Figure 4.16: Sign Up Page

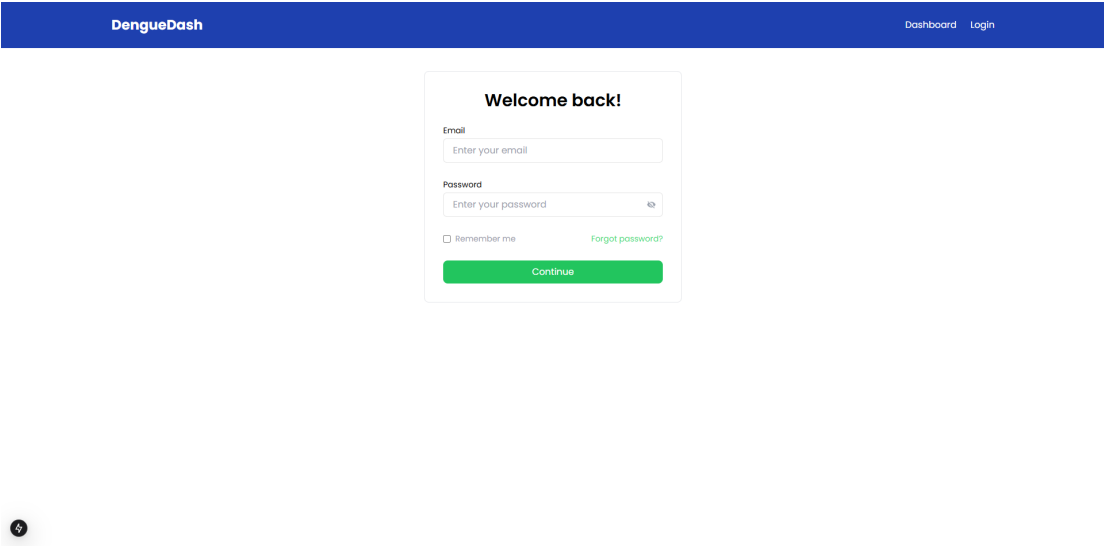

Figure 4.17: Login Page

4.6.3 Encoder Interface

Case Report Form

Figures 4.18 and 4.19 show the digitized counterpart of the form obtained from the Iloilo Provincial Epidemiology and Surveillance Unit. As the system aims to support expandability for future features, some fields were modified to accommodate more detailed input. It is worth noting that all of the included fields adhere to the latest Philippine Integrated Disease and Surveillance Response (PIDS) Dengue Forms, which the referenced form was based on. By doing this, if implemented on a national scale, the transition between targeted users will be easier. Moreover, the case form includes the patient's basic information, dengue vaccination status, consultation details, laboratory results, and the outcome. On the other hand, encoders can also create case records using a "bulk upload" feature that makes use of a formatted CSV file template. As shown in Figure 4.20, an encoder can download the template using the "Download Template" button, and insert multiple records inside the file, then upload it by clicking the "Click to upload" button. The web application automatically checks the file for data inconsistencies and validation.

The screenshot displays the 'Case Report Form' interface within the 'DengueDash' application. The left sidebar shows the navigation menu with options like 'Analytics', 'Forms', 'Data Tables', and 'Settings'. The main content area is titled 'Case Report Form' and features a 'Bulk Upload' button. The form is organized into two tabs: 'Personal Information' and 'Clinical Status'. Under 'Personal Information', there are two sub-sections: 'Personal Detail' and 'Address'. 'Personal Detail' includes input fields for First Name, Middle Name, Last Name, Suffix, Sex (a dropdown menu), Civil Status (a dropdown menu), and Date of Birth (a date picker). 'Address' includes dropdown menus for Region, Province, City, and Barangay, as well as input fields for Street and House No. The 'Clinical Status' tab contains a 'Vaccination' section with date pickers for 'Date of First Vaccination' and 'Date of Last Vaccination'. A 'Next' button is located at the bottom right of the form. The user's profile information, 'Elizabeth Thomas Ra...' and 'elwis@example.com', is visible in the bottom left corner.

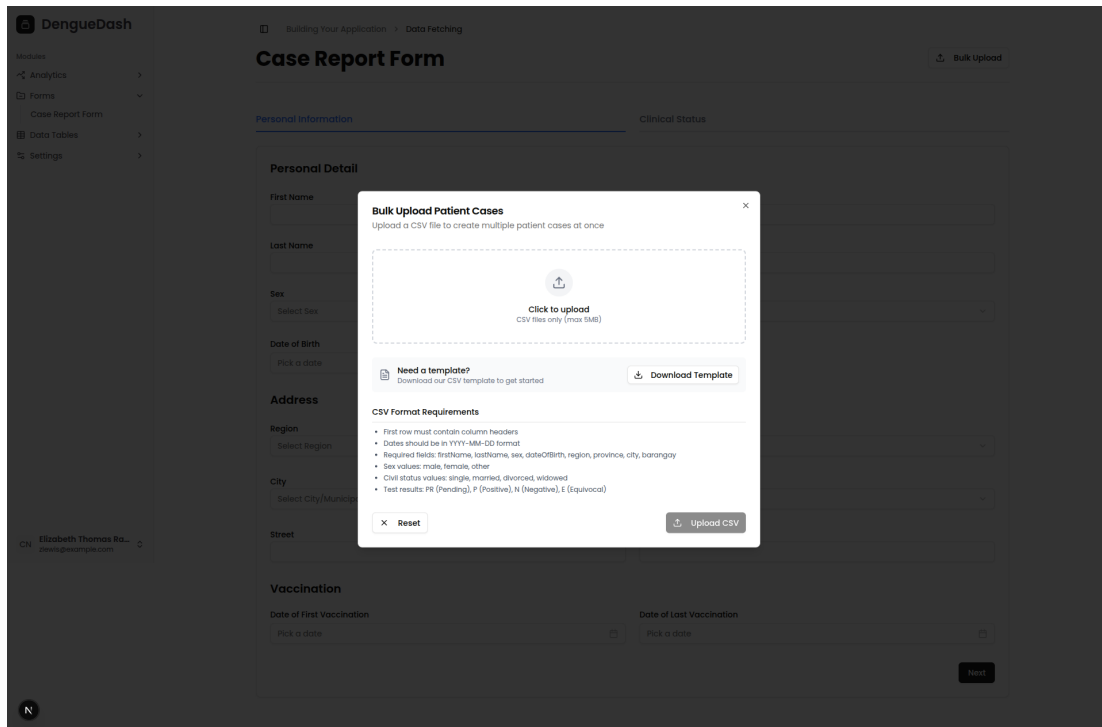

Figure 4.20: Bulk Upload of Cases using CSV

977 Browsing, Update, and Deletion of Records

978 Once the data generated from the case report form or the bulk upload is vali-
 979 dated, it will be assigned as a new case and can be accessed through the Dengue
 980 Reports page, as shown in Figure 4.21. The said page displays basic information
 981 about the patient related to a specific case, including their name, address, date
 982 of consultation, and clinical and case classifications. It is also worth noting that
 983 it only shows cases the user is permitted to view. For example, in a local Disease
 984 Reporting Unit (DRU) setting, the user can only access records that belong to
 985 the same DRU. On the other hand, in a consolidated surveillance unit such as a
 986 regional, provincial, or city quarter, its users can view all the records from all the
 987 DRUs that report to them. Moving forward, Figure 4.22 shows the detailed case
 988 report of the patient on a particular consultation date.

To update the case, the user can click the "Update Case" button, where a dialog will appear, and the updateable fields will be shown. It is worth noting that in this case, only fields under Laboratory Results and Outcome are included since they are the only ones that are time-based, where the result may change in the future. After updating, a prompt will show confirming the action of the user. Moving forward, to delete a case record, the user must click the "Delete Case" button, and a prompt verifying the action will appear. After confirming, the case will be deleted permanently.

997 **Forecasting**

998 The main highlight of the web application’s feature is the Forecasting Page. This
999 is where users can forecast dengue cases for the next following weeks. To predict,
1000 the application utilizes the exported LSTM model in a Keras format derived
1001 from training the consolidated data from the database. It requires the recent
1002 weekly dengue cases, weather variable data (temperature, humidity, and rainfall)
1003 based on the window size, and future weather data through OpenWeatherMap
1004 API. However, due to limitations imposed in the current plan subscribed in the
1005 API, only the next 16 days of weather data can be fetched. As a result, the web
1006 application can only make a two-week prediction. Moving forward, the Forecasting
1007 page, as shown in Figure 4.25, introduces a user-friendly interface that shows the

1008 current cases for the week, and the predictions for the next two weeks with a range
1009 of 90 percent to 110 percent confidence interval that is presented in a simple but
1010 organized manner. There is also a line chart that shows the number of cases from
1011 the last 5 weeks plus the forecasted weekly cases. In addition, the current weather
1012 data for a specific week is also shown as well as the the forecasted weather data
1013 fetched from the said API. Lastly, locations where dengue cases have been reported
1014 for the current week are listed in the Location Risk Assessment component.

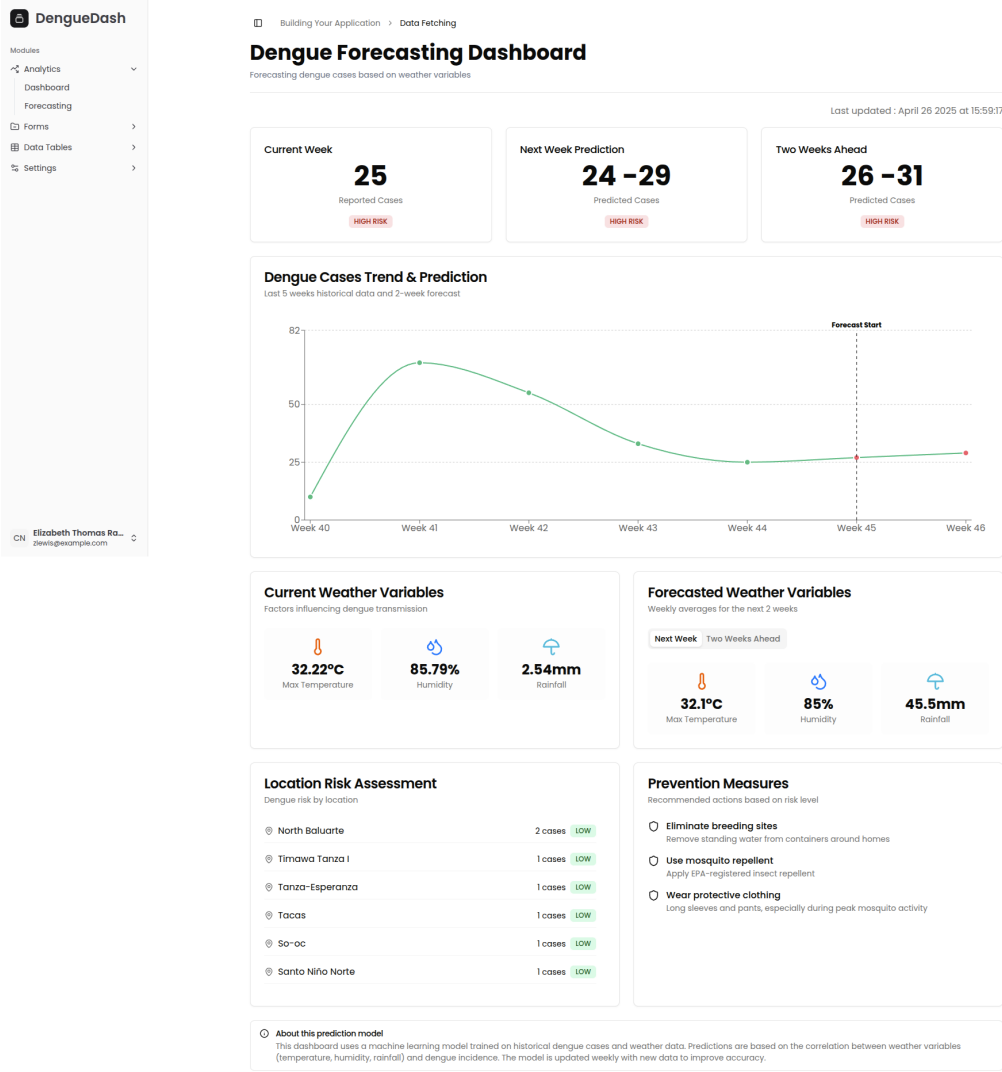

Figure 4.25: Forecasting Page

1015 **4.6.4 Admin Interface**

1016 **Retraining**

1017 With LSTM being the best-performing model among the models used in forecast-
1018 ing dengue cases, it is the model chosen to power the prediction and retraining
1019 of the consolidated data within the web application. Since the retraining process
1020 consumes a lot of processing power and requires a more advanced understanding
1021 of how it works, it was decided that the said feature should only be available
1022 to admin users. Furthermore, the retraining component in the Forecasting page
1023 includes three additional components that include the configuration of LSTM pa-
1024 rameters (Figure 4.26), the actual retraining of the consolidated data from the
1025 database (Figure 4.27), and the results of the retraining that shows the current
1026 and previous model metrics depending on the parameters entered (Figure 4.28).
1027 It is also worth noting that when trained, the model used a seeded number to
1028 promote reproducibility.

1029 **Managing Accounts**

1030 Proper management of accounts is important to protect the integrity and confi-
1031 dentiality of data. Thus, it is crucial for administrators to track their users and
1032 control the flow of information. As discussed in the user registration of encoders,
1033 admin users from a specific DRU or surveillance have the power to grant them
1034 access to the web application. Figure 4.30 illustrates the interface for this sce-
1035 nario, as the admins can approve or reject their applications. Once approved,
1036 these users can access the features given to encoders and may be promoted to
1037 have administrative access, as shown in Figure 4.31. Otherwise, once deleted, the
1038 email will be blacklisted and is illegible to use when creating another account.
1039 Once deleted, the email will be blacklisted and cannot be used when creating
1040 another account. The same figure also shows the expanded details of the user,
1041 which include personal information and brief activity details within the system.

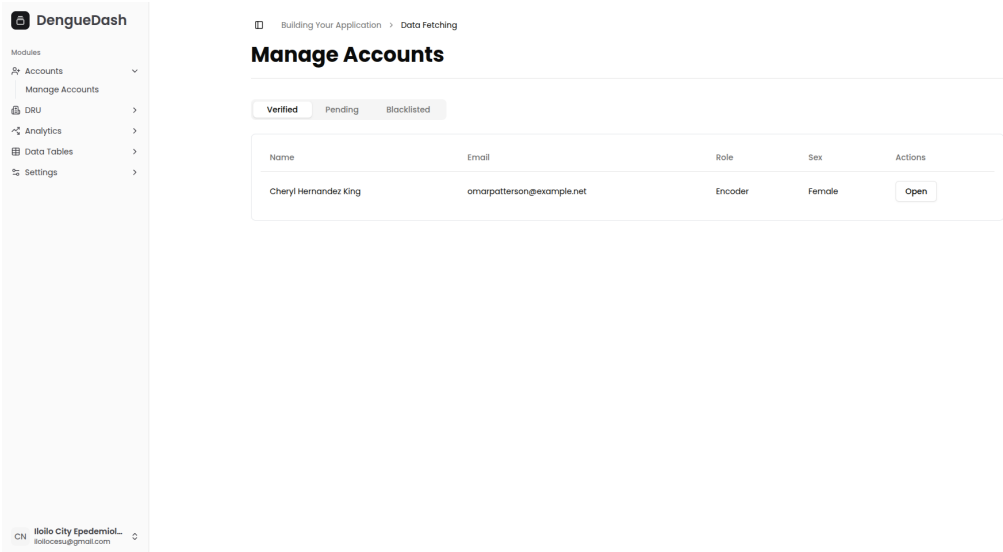

Figure 4.29: List of Verified Accounts

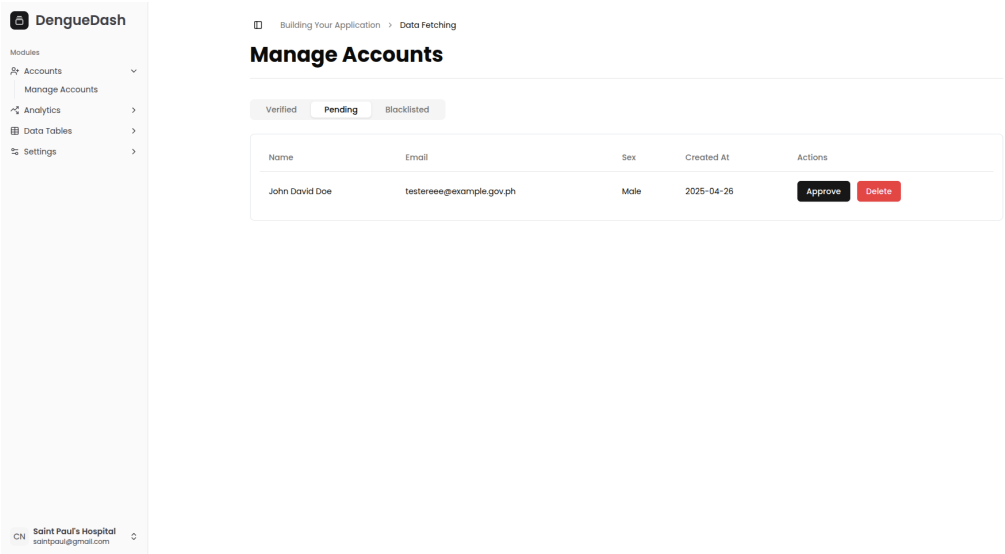

Figure 4.30: List of Pending Accounts

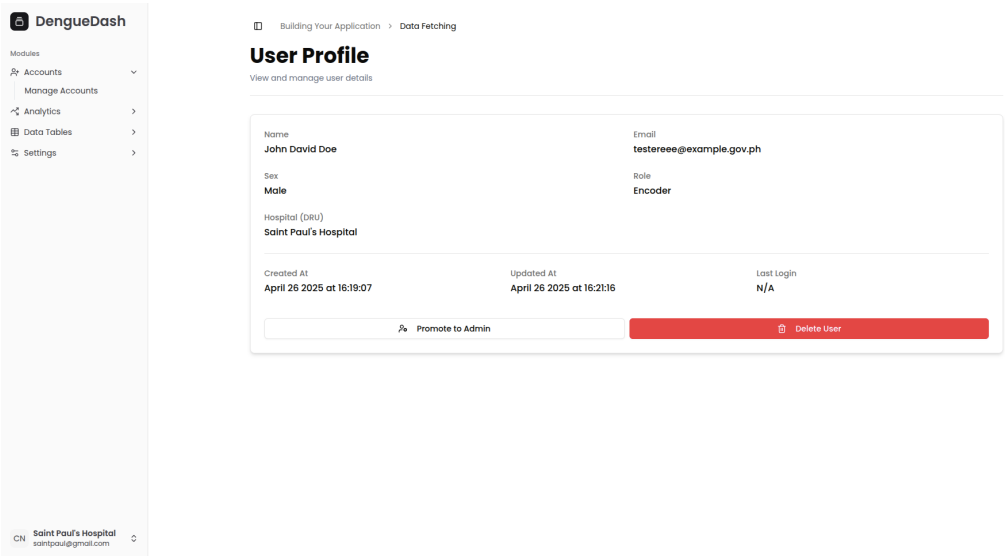

Figure 4.31: Account Details

1042 **Managing DRUs**

1043 Unlike the registration of encoder accounts, the creation of Disease Reporting
1044 Units can only be done within the web application, and the user performing the
1045 creation must be an administrator of a surveillance unit. Figure 4.32 presents the

1046 fields the admin user must fill out, and once completed, the new entry will show
1047 as being managed by that unit, as shown in Figure 4.33. Figure 4.34, on the other
1048 hand, shows the details provided in the registration form as well as its creation
1049 details. There is also an option to delete the DRU, and when invoked, all the
1050 accounts being managed by it, and the cases reported under those accounts will
1051 be deleted.

1052 4.7 User Testing

1053 To evaluate the usability of the system, the System Usability Scale (SUS) was
 1054 utilized. SUS is a Likert-scale-based questionnaire comprising 10 items that are
 1055 critical to assessing system usability. A total of five participants completed the sur-
 1056 vey. Their responses were processed following the step-by-step calculation method
 1057 adopted from (Babich, 2015). The resulting usability scores for each participant
 1058 are shown in Table 4.5.

Participant	Usability Score
1	95.0
2	90.0
3	85.0
4	87.5
5	85.0
Average	88.5

Table 4.5: Computed System Usability Scores per Participant

1059 The average System Usability Scale (SUS) score across systems is typically
 1060 68 (Babich, 2015). In this testing, the system achieved an average SUS score
 1061 of 88.5, indicating a highly positive user experience. This score suggests that
 1062 participants found the system not only enjoyable to use but also intuitive enough

1063 to recommend to others. Furthermore, it demonstrates that the system is suitable
1064 for real-world applications without presenting significant complexity for first-time
1065 users.
